**Abstract:** An evaluation of  $A = 16\text{--}17$  was published in *Nuclear Physics A564* (1993), p. 1. This version of  $A = 16$  differs from the published version in that we have corrected some errors discovered after the article went to press. The introduction and introductory tables have been omitted from this manuscript. Reference key numbers have been changed to the NNDC/TUNL format.

## Table of Contents for $A = 16$

*Below is a list of links for items found within the PDF document. The introductory [Table 2](#) is available on this website via the link.*

**A. Nuclides:**  $^{16}\text{He}$ ,  $^{16}\text{Li}$ ,  $^{16}\text{Be}$ ,  $^{16}\text{B}$ ,  $^{16}\text{C}$ ,  $^{16}\text{N}$ ,  $^{16}\text{O}$ ,  $^{16}\text{F}$ ,  $^{16}\text{Ne}$ ,  $^{16}\text{Na}$ ,  $^{16}\text{Mg}$ ,  $^{16}\text{Al}$ ,  $^{16}\text{Si}$

**B. General Tables:**

[Table 16.1](#): General table for  $^{16}\text{C}$

[Table 16.4](#): General table for  $^{16}\text{N}$

[Table 16.12](#): General table for  $^{16}\text{O}$

[Table 16.29](#): General table for  $^{16}\text{F}$  and  $^{16}\text{Ne}$

**C. Tables of Recommended Level Energies:**

[Table 16.2](#): Energy levels of  $^{16}\text{C}$

[Table 16.5](#): Energy levels of  $^{16}\text{N}$

[Table 16.13](#): Energy levels of  $^{16}\text{O}$

[Table 16.30](#): Energy levels of  $^{16}\text{F}$

[Table 16.32](#): Energy levels of  $^{16}\text{Ne}$

**D. References**

**E. Figures:**  $^{16}\text{C}$ ,  $^{16}\text{N}$ ,  $^{16}\text{O}$ ,  $^{16}\text{F}$ , Isobar diagram

**F. Erratum to the Publication:** [PS](#) or [PDF](#)

## $A = 16$ theoretical

Because of the very large body of theoretical work that has been carried out for the  $A = 16$ , and the importance of the spherical shell model in this work, a general discussion of the shell model description of  $A = 16$  nuclei is provided here.<sup>1</sup>

The spherical shell-model provides a complete basis for the description of nuclear states. It is convenient to use harmonic oscillator single-particle wave functions since the coordinate transformations necessary to separate spurious center of mass states, to relate shell-model to cluster-model wave functions and so on can be made exactly. Configurations are classified by the number of oscillator quanta that they carry beyond the minimum allowed by the Pauli Principle as  $0\hbar\omega$ ,  $1\hbar\omega$ ,  $2\hbar\omega \dots$  excitations. Non-spurious states of  $A = 16$  in general involve admixtures of  $nph$  configurations but the lowest excitations of each isospin can, with the exception of the  $K^\pi = 0^-$  band with the  $^{16}\text{O}$  9.58 MeV  $1^-$  state as bandhead, be thought of as dominantly  $p^{-n}(sd)^n$  excitations. In fact, the lowest eigenstates of an  $n\hbar\omega$  calculation can usually be written economically in terms of product states of low-lying  $p^{-n}$  and  $(sd)^n$  eigenstates. In the simplest version of this weak-coupling model, one identifies the  $p^{-n}$  and  $(sd)^n$  eigenstates with the physical states of the relevant nuclei and takes the diagonal expectation value of  $H_p + H_{sd}$  from the known masses. The contribution from the cross-shell, or particle-hole, interaction can often be quite reliably estimated by using  $ph$  matrix elements extracted from the nominal  $1p1h$  states of  $^{16}\text{O}$  or  $^{16}\text{N}$ .

The  $2p2h$  states with  $T = 0$  and  $T = 1$  cannot, in general, be described in terms of the simple weak-coupling model, although there are examples to which such a description can be applied. Shell-model calculations which use empirical interactions fitted to data on  $1\hbar\omega$  excitations in the mass region do, however, produce  $2p2h T = 1$  states in one-to-one correspondence with the lowest positive-parity states of  $^{16}\text{N}$  (see Table 16.5). They also produce  $T = 0$   $2p2h$  states starting at around 12 MeV in  $^{16}\text{O}$ . In this case, the  $2p2h$  states are interleaved with  $4p4h$  states which begin at lower energies. The lowest  $2p2h T = 0$  states can be related in energy to the 14.82 MeV  $6^+$  state which is strongly populated by the addition of a stretched  $d_{5/2}^2$  pair in the  $^{14}\text{N}(\alpha, d)^{16}\text{O}$  reaction. The lowest six  $2p2h T = 2$  states can be very well described in this way.

Weak-coupling ideas can be extended to the lowest  $3p3h$  and  $4p4h$  states. Since the 3 and 4 particle (or hole) configurations are strongly configuration mixed in the  $jj$ -coupling scheme, the  $ph$  interaction is usually represented in the simple monopole form  $E_{ph} = a + bt_p.t_h$  plus a small attractive Coulomb contribution. The  $ph$  interaction then gives a repulsive contribution of  $9a$  and  $16a$  to  $3p3h$  and  $4p4h$  configurations and separates the  $T = 0$  and  $T = 1$   $3p3h$  states by  $b$  MeV. The empirical values of  $a$  and  $b$  are  $a \approx 0.4$  MeV and  $b \approx 5$  MeV, which put the  $4p4h 0^+$  state and the  $3p3h 1^-$  states close to experimental candidates at 6.05, 12.44 and 17.28 MeV respectively, each of which is the lowest member of a band.

The weak-coupling states can be used as a basis for shell-model calculations, but the elimination of spurious center-of-mass motion is approximate even within an oscillator framework; orbits outside the  $p(sd)$  space are needed and can be important components of states of physical interest. If complete  $n\hbar\omega$  spaces are used, the choice of basis can be one of computational convenience. A more physical LS-coupled basis is obtained by classifying the states according to the Wigner

<sup>1</sup> We are very grateful to Dr. John Millener for providing these comments on the shell model for the  $A = 16$  system.

supermultiplet scheme ( $SU4 \supset SU2 \times SU2$  symmetry  $[\tilde{f}]$  in spin-isospin space) and the  $SU3$  symmetry  $(\lambda \mu)$  of the harmonic oscillator. States with the highest spatial symmetry  $[f]$  maximize the number of spatially symmetric interacting pairs to take advantage of the fact that the NN interaction is most strongly attractive in the relative  $0s$  state and weak or repulsive in relative  $p$  states. These symmetries are broken mainly by the one-body spin-orbit interaction. In  $np$  and  $nh$  calculations the lowest states are dominated by the  $[f] (\lambda \mu)$  configurations  $[n] (2n\ 0)$  and  $[4^2 4 - n] (0\ n)$  respectively (these symmetries are very good if the one-body spin-orbit interaction is turned off). In  $nph$  calculations, the lowest states are dominated by the highest spatial symmetry allowed for given isospin  $T$  and  $(2n\ n)$   $SU3$  symmetry. These states are identical to harmonic oscillator cluster-model states with  $2n$  quanta on the relative motion coordinate between the  $nh$  core and the  $np$  cluster. States with a large parentage to the ground state of the core should be seen strongly in the appropriate transfer reaction.

In the above, a basic  $n\hbar\omega$  (mainly  $nph$ ) shell-model structure has been matched, through characteristic level properties and band structures, with experimental candidates. The mixing between shell-model configurations of different  $n\hbar\omega$  is of several distinct types.

First, there is direct mixing between low-lying states with different  $nph$  structure; the  $p^2 \rightarrow (sd)^2$  mixing matrix elements ( $SU3$  tensor character mainly  $(4\ 2)$ ) are not large (up to a few MeV) although the mixing can be large in cases of near degeneracy.

A second type of mixing is more easily understood by reference to cluster models in which an oscillator basis is used to expand the relative motion wave function. To get a realistic representation of the relative motion wave function for a loosely-bound state or an unbound resonance requires many oscillators up to high  $n\hbar\omega$  excitation. A related problem, which also involves the radial structure of the nucleus, occurs for the expansion of deformed states (of which cluster states are an example) in a spherical oscillator (shell-model) basis; e.g., deformed Hartree-Fock orbits may require an expansion in terms of many oscillator shells. It is difficult to accommodate this type of radial mixing in conventional shell-model calculations, but symplectic  $Sp(6,R)$  shell-models, in which the  $SU3$  algebra is extended to include  $1p1h\ 2\hbar\omega$  monopole and quadrupole excitations, do include such mixing up to high  $n\hbar\omega$ .

A third type of mixing involves the coupling of  $nph$  excitations to high-lying  $(n + 2)\hbar\omega$  configurations via the strong  $(\lambda \mu) = (2\ 0)$  component of the  $p^2 \rightarrow (sd)^2$  interaction. In the full  $(0 + 2 + 4)\hbar\omega$  calculations, the large (30-45%)  $2p2h$  admixtures in the ground state are mainly of the  $(2\ 0)$  type, which are intimately related to the ground-state correlations of RPA theory, and lead to the enhancement (quenching) of  $\Delta T = 0$ ,  $\Delta S = 0$  (otherwise) excitations at low momentum transfer.

For most detailed structure questions, a shell-model calculation is required to include the relevant degrees of freedom. For example, (1990HA35) address two important problems with complete  $(0 + 2 + 4)\hbar\omega$  and  $(1 + 3)\hbar\omega$  model spaces. One is the rank-zero  $^{16}\text{N}(0^-) \rightarrow {}^{16}\text{O}(gs)$   $\beta$  decay and the inverse  $\mu$  capture which receive large two-body meson-exchange current contributions. The other is the distribution of M1 and Gamow-Teller strength based on the  ${}^{16}\text{O}$  ground state; this is a complicated problem which involves  $2p2h \dots$  admixtures in the ground state which break  $SU4$  symmetry.

Many interesting structure problems remain. A detailed understanding of the shapes and magnitudes of inelastic form factors is lacking, particularly the shapes at momentum transfers beyond  $2 \text{ fm}^{-1}$ . Even in the relatively simple case of M4 excitations, much studied via  $(e, e')$ ,  $(p, p')$  and  $(\pi, \pi')$  reactions, a rather low value of the oscillator parameter  $b$  is required to describe the form factor. Also, the configuration mixing which splits the  $4^-; T = 0$  strength into two major components and causes isospin mixing has not been satisfactorily described by a shell-model calculation. Similar interesting problems occur for isospin-mixed negative-parity states near 13 MeV excitation energy. It is worth noting that, to avoid some serious consistency problems, the large shell-model calculations have omitted orbits outside the  $p(sd)$  space except in as much to cleanly separate spurious center-of-mass states. A consistent treatment of  $1p1h$  and  $2p2h$  correlations in multi- $\hbar\omega$  shell-model spaces remains a challenging question.

**$^{16}\text{He}$**   
(not illustrated)

This nucleus has not been observed. See ([1982AV1A](#), [1983ANZQ](#), [1986AJ04](#)).

**$^{16}\text{Li}$**   
(not illustrated)

This nucleus has not been observed. Shell model studies ([1988POZS](#)) are used to predict  $J^\pi$  and the magnetic dipole moment.

**$^{16}\text{Be}$**   
(not illustrated)

This nucleus has not been observed. Its atomic mass is calculated to be 59.22 MeV. It is then unstable with respect to breakup into  $^{14}\text{Be} + 2\text{n}$  by 2.98 MeV. See ([1974TH01](#), [1986AJ04](#), [1987SA15](#)). The first three excited states with  $J^\pi = 2^+, 4^+, 4^+$  are calculated to be at 1.90, 5.08, and 6.51 MeV using a  $(0+1)\hbar\omega$  space shell model ([1985PO10](#)).

**$^{16}\text{B}$**   
(not illustrated)

This nucleus has not been observed in the 4.8 GeV proton bombardment of a uranium target. It is particle unstable. Its mass excess is predicted to be 37.97 MeV; it would then be unstable with respect to decay into  $^{15}\text{B} + \text{n}$  by 0.93 MeV. See ([1985WA02](#), [1986AJ04](#)). The ground state is predicted to have  $J^\pi = 0^-$  and the first three excited states are predicted to lie at 0.95, 1.10, and 1.55 MeV [ $J^\pi = 2^-, 3^-, 4^-$ ] in a  $(0+1)\hbar\omega$  space shell model calculation. See ([1983ANZQ](#), [1985PO10](#), [1986AJ04](#)). Predicted masses and excitation energies for higher isospin multiplets for  $9 \leq A \leq 60$  are included in the compilation ([1986AN07](#)). An experiment ([1985LA03](#)) involving in-flight identification of fragments from 44 MeV/u  $^{40}\text{Ar}$  found no trace of  $^{18}\text{B}$  or  $^{16}\text{B}$  and provides strong evidence that  $^{16}\text{B}$  is particle-unstable.

<sup>16</sup>C  
(Figs. 1 and 5)

GENERAL: See Table 16.1.

The half life of  $^{16}\text{C}$  is  $0.747 \pm 0.008$  sec. It decays to  $^{16}\text{N}^*(0.12, 3.35, 4.32)$  [ $J^\pi = 0^-, 1^+, 1^+$ ]: see Table 16.3 and (1993CH06). See also (1986AJ04) and see (1986KI05, 1988WA1E, 1992WA1L) for theoretical discussions of extended shell-model calculations of  $0^+ \rightarrow 0^-$  transitions and determination of the mesonic enhancements  $\varepsilon_{\text{mec}}$  of the time-like component of the axial current. See also (1992TO04) and see  $^{16}\text{N}$ , reaction 1.

States of  $^{16}\text{C}$  observed in this reaction are displayed in Table 16.2. See also Table 16.3 of (1982AJ01).

(1985BE31) used negative kaons of 450 MeV/c to produce  $\Sigma$  hypernuclear states, which they interpreted as  $\Sigma^-$  particles in the  $p_{3/2}$  and  $p_{1/2}$  orbits of the  $^{16}\text{C}$  hypernucleus. Their energy splitting was used to constrain the  $\Sigma^-$  spin-orbit coupling.

(1986HA26) performed a systematic shell-model analysis of  $\Sigma$ -hypernuclear states, in which they deduced a  $\Sigma\text{N}$ -spin-orbit interaction about twice as strong as the one for the nucleon. (1986MA1J) reached a similar conclusion after extracting the one-particle spin-orbit splitting  $\varepsilon_\Sigma = \varepsilon^\Sigma p_{1/2} - \varepsilon^\Sigma p_{3/2}$ . (1987WU05) used the continuum shell-model to study competition between resonant and quasi-free  $\Sigma$ -hypernuclear production. The observed structures in the excitation spectra are essentially accounted for by the quasi-free mechanism alone. (1989DO1I) perform a series of shell model calculations of energy spectra of p-shell  $\Sigma$  hypernuclei, starting with several different parametrizations of the  $\Sigma\text{N}$  effective interaction. Production cross sections are estimated using DWBA. They suggest experiments to resolve open questions regarding the  $\Sigma\text{N}$  and  $\Sigma$ -nucleus interactions. (1989HA32) uses the recoil continuum shell model to calculate in-flight  $\Sigma$  hypernuclei production of this reaction (and others). They needed to modify the  $\Sigma\text{N}$  central interaction to fit data.

Coupled channels (CC) calculations for  $\Sigma$ -hypernuclear spectra give an energy integrated cross section which is about 1.7 times the experimental value (1987HA40). (1988HA44) report CC calculations emphasizing the proper treatment of the  $\Sigma$  continuum states. They find that a weak  $\Sigma$  central potential and a comparable  $\Sigma\Lambda$  conversion potential are required to describe experiment.

$6.109 \pm 15$	$(2^+, 3^-, 4^+)$	$\Gamma \leq 25$		2

 Table 16.3: The  $\beta^-$  decay of  $^{16}\text{C}$ 

Decay to $^{16}\text{N}^*$ (MeV)	$J^\pi$	Branch (%)	$\log ft$
0.120	$0^-$	$0.68_{-0.11}^{+0.09}$ <sup>a</sup>	$6.70_{-0.05}^{+0.07}$
0.298	$3^-$	$< 0.5$ <sup>b</sup>	$> 6.83$
0.397	$1^-$	$< 0.1$ <sup>a</sup>	$> 7.46$
3.35	$1^+$	$84.4 \pm 1.7$ <sup>b</sup>	$3.551 \pm 0.012$
4.32	$1^+$	$15.6 \pm 1.7$ <sup>b</sup>	$3.83 \pm 0.05$

<sup>a</sup> (1983GA03). See also (1984GA1A).

<sup>b</sup> (1976AL02).

<sup>16</sup>N  
(Figs. 2 and 5)

GENERAL: See Table 16.4.

For a comparison of analog states in <sup>16</sup>N and <sup>16</sup>O, see (1983KE06, 1983SN03).

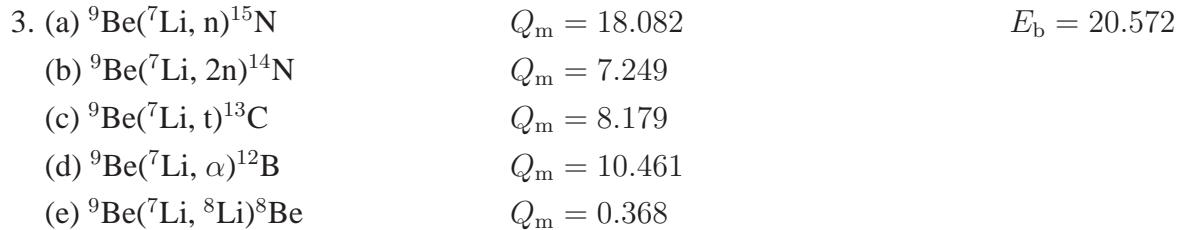

The half-life of <sup>16</sup>N is  $7.13 \pm 0.02$  sec: see Table 16.3 in (1971AJ02). From the unique first-forbidden character of the  $\beta$  decay [see Table 16.25 and (1984WA07)], <sup>16</sup>N must have  $J^\pi = 2^-$ : see <sup>16</sup>O, reaction 39. See also (1985HE08, 1988BA15).

The  $\beta$ -decay of <sup>16</sup>N\*(0.12) [ $J^\pi = 0^-$ ] has been measured (1983GA18, 1985HA22); adopted value:  $\lambda_\beta = 0.489 \pm 0.020 \text{ sec}^{-1}$  (1985HE08). The relationship of this rate to that for  $^{16}\text{O}(\mu^-, \nu)^{16}\text{N}(0^-)$  [see reaction 18] and the fact that the large values of these rates support the prediction (1978GU05, 1978GU07, 1978KU1A) of a large ( $\approx 60\%$ ) enhancement over the impulse approximation (e.g.,  $\varepsilon_{\text{mec}} = 1.60$ ) has been the subject of a great deal of theoretical study, see, e.g. (1981TO16, 1986KI05, 1986TO1A, 1988WA1E, 1990HA35). The work of (1990HA35, 1992WA1L) is a culmination of present knowledge on the determination and interpretation of  $\varepsilon_{\text{mec}}$ . See also (1992TO04). A branching ratio  $R(0^- \rightarrow 1^-)/(0^- \rightarrow 0^+) = 0.09 \pm 0.02$  has been reported (1988CH30), implying  $\log ft = 4.25 \pm 0.10$  for the  $0^- \rightarrow 1^-$  transition to the <sup>16</sup>O 7.12-MeV level.

Gamma rays with  $E_\gamma = 120.42 \pm 0.12$ ,  $298.22 \pm 0.08$  and  $276.85 \pm 0.10$  keV from the ground state decays of <sup>16</sup>N\*(0.12, 0.30) and the decay of the state at  $397.27 \pm 0.10$  keV to the first excited state have been studied.  $\tau_m$  for <sup>16</sup>N\*(0.30, 0.40) are, respectively,  $133 \pm 4$  and  $6.60 \pm 0.48$  psec. See (1986AJ04). Cross section measurements for <sup>7</sup>Li + <sup>11</sup>B at  $E(\text{c.m.}) = 1.45\text{--}6.10$  MeV have been reported (1990DA03).

At incident <sup>7</sup>Li energies of 40 MeV, neutron yields at  $0^\circ$  for reactions (a) and (b) are 50 to 70 times smaller than for 40 MeV deuteron-induced reactions on <sup>9</sup>Be (1987SC11). For reactions (c, d, e) see (1982AJ01).

---

4. ${}^9\text{Be}({}^9\text{Be}, \text{np}){}^{16}\text{N}$	$Q_m = 1.652$
---	---------------

Cross sections were measured for characteristic  ${}^{16}\text{N}$  gamma rays for incident  ${}^9\text{Be}$  energies  $E_{c.m.} = 1.4\text{--}3.4$  MeV. The n, p and all other two-particle emission channels are enhanced by a factor of 2–3 relative to predictions of DWBA calculations ([1988LA25](#)).

5. ${}^{10}\text{B}({}^7\text{Li}, \text{p}){}^{16}\text{N}$	$Q_m = 13.986$
--	----------------

See Table 16.6 and ([1982AJ01](#)).

---

Fig. 2: Energy levels of  ${}^{16}\text{N}$ . In these diagrams, energy values are plotted vertically in MeV, based on the ground state as zero. Uncertain levels or transitions are indicated by dashed lines; levels which are known to be particularly broad are cross-hatched. Values of total angular momentum  $J$ , parity, and isobaric spin  $T$  which appear to be reasonably well established are indicated on the levels; less certain assignments are enclosed in parentheses. For reactions in which  ${}^{16}\text{N}$  is the compound nucleus, some typical thin-target excitation functions are shown schematically, with the yield plotted horizontally and the bombarding energy vertically. Bombarding energies are indicated in laboratory coordinates and plotted to scale in cm coordinates. Excited states of the residual nuclei involved in these reactions have generally not been shown; where transitions to such excited states are known to occur, a brace is sometimes used to suggest reference to another diagram. For reactions in which the present nucleus occurs as a residual product, excitation functions have not been shown; a vertical arrow with a number indicating some bombarding energy, usually the highest, at which the reaction has been studied, is used instead. Further information on the levels illustrated, including a listing of the reactions in which each has been observed, is contained in the master table, entitled “Energy levels of  ${}^{16}\text{N}$ ”.

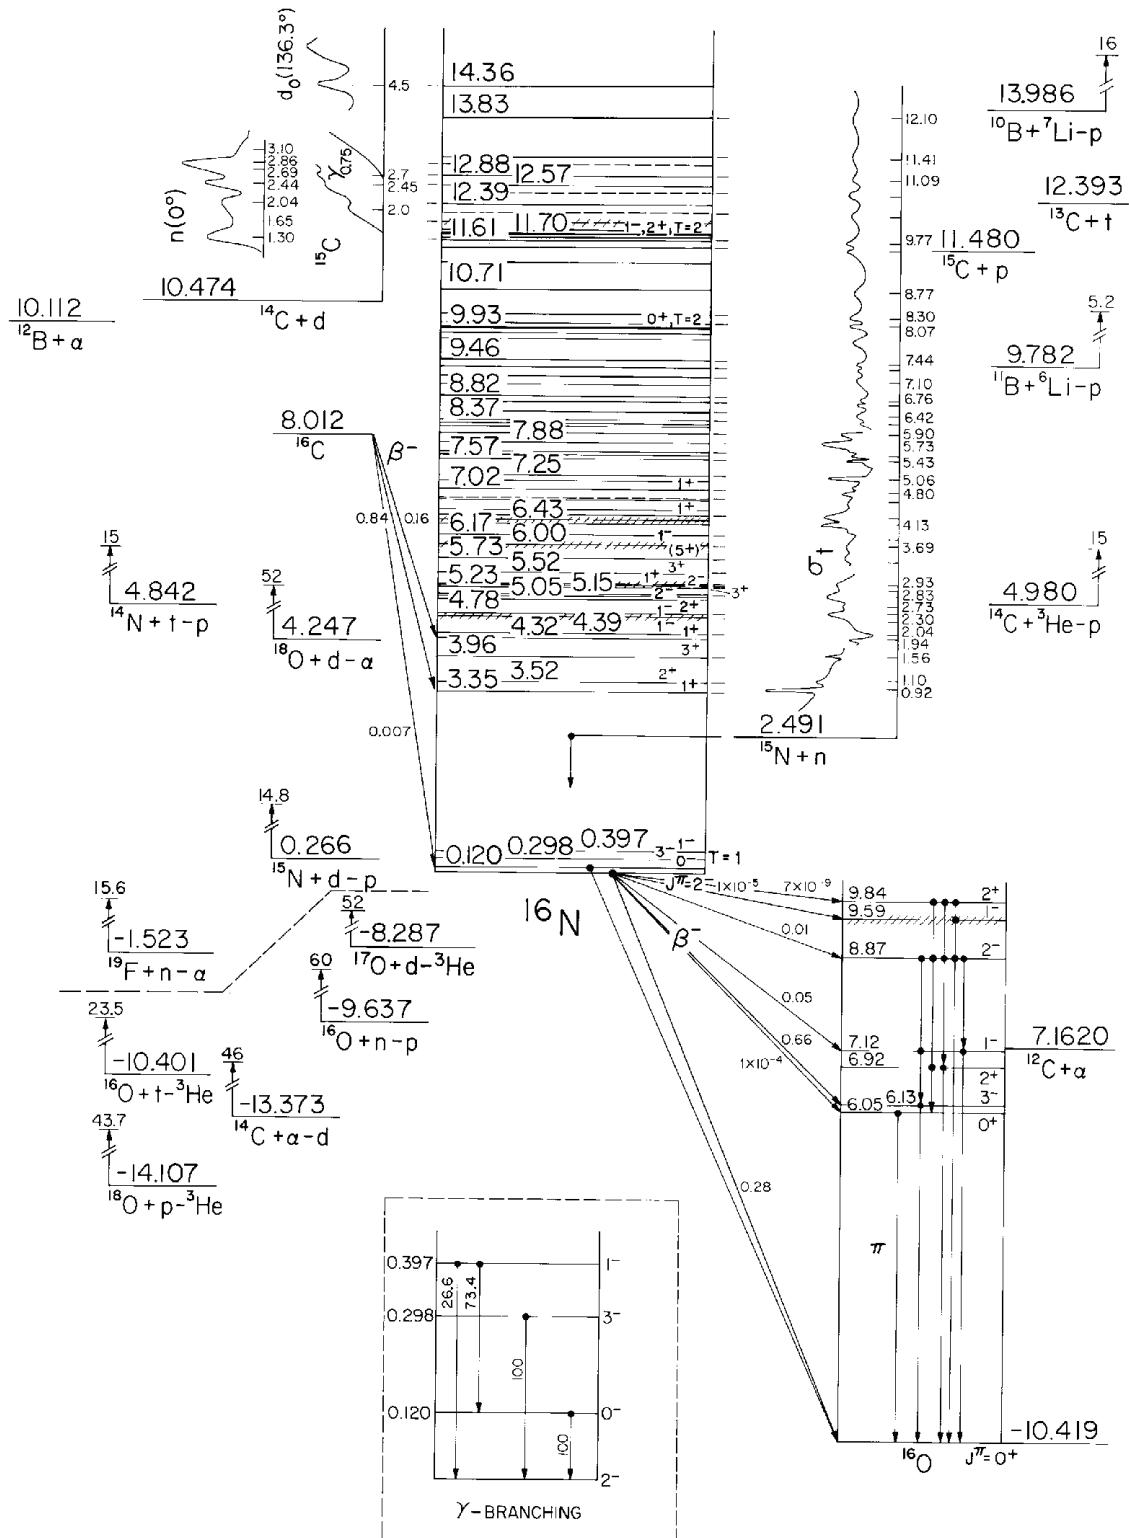

Table 16.5: Energy Levels of  $^{16}\text{N}$ 

$E_x$ (MeV $\pm$ keV)	$J^\pi; T$	$\tau$ or $\Gamma_{\text{c.m.}}$ (keV)	Decay	Reactions

<sup>a</sup> See also Table 16.6.

<sup>b</sup> See also Table 16.7.

<sup>c</sup> May be a doublet. See (1985BLZY) and see Table 16.15.

<sup>d</sup> Probably the analog of  $^{16}\text{O}^*(18.029)$ , D.J. Millener, private communication.

<sup>e</sup> May be a  $2^-$ ,  $5^+$  doublet – the analogs of  $^{16}\text{O}$  states at  $E_x = 18.454$  and  $18.640$  MeV,  $J^\pi = (2^-)$  and  $5^+$ , respectively (D.J. Millener, private communication).

<sup>f</sup> (1987AZZZ) and D.J. Millener, private communication.

$^{16}\text{N}$  spectra were measured for incident  $^{16}\text{O}$  energies of 900 MeV/nucleon. Transitions to the low-lying GDR, the quasi-elastic, and the  $\Delta$ -regions were observed (1987EL14).

Table 16.6: States of  $^{16}\text{N}$  from  $^{10}\text{B}(^7\text{Li}, \text{p})$ <sup>a</sup>

$E_x$ <sup>b</sup> (MeV)	$J$ <sup>c</sup>	$E_x$ <sup>b</sup> (MeV)	$J$ <sup>c</sup>
0		5.142	e
0.124		5.230	f
0.296		5.318	0, 1
0.400		5.525	4, 3 <sup>g</sup>
3.352	c	5.734	h
3.524	c	6.002	1 <sup>f</sup>
3.964	c	6.172	i
4.321	c	6.374	c
4.392	c	6.504	c
4.785	c	6.608	4 <sup>j</sup>
5.054	1, 2 <sup>d</sup>		

<sup>a</sup> For references see (1986AJ04).

<sup>b</sup>  $\pm 3$  keV.

<sup>c</sup> Based on the assumption that the angle-integrated cross section is proportional to  $2J + 1$ . States labelled c have  $J$  consistent with known values.

<sup>d</sup> If a doublet,  $J = 1$  and 0.

<sup>e</sup> Doublet (1986AJ04).

<sup>f</sup> Narrow state.

<sup>g</sup> If a doublet, and if one state is  $3^+$ , the second member would have  $J = 0$ .

<sup>h</sup> If a doublet of which one member is  $5^+$ , the other would have  $J = 2$  (1, 3).

<sup>i</sup> May be a doublet (1986AJ04).

<sup>j</sup>  $J = 4$ , if a single state.

Differential cross sections measured (1986AN30) at  $E_\alpha = 118$  MeV were analyzed using DWBA calculations with microscopic form factors to obtain  $J^\pi$  and to locate multiparticle-multipole strength in  $^{16}\text{N}$ : see Table 16.7. Measurements at  $E_\alpha = 34.9$  MeV are summarized in Table 16.5 of (1986AJ04). See also (1988MIZY, 1988BRZY).

5.512 ± 5		(1, 2, 3) <sup>+</sup>			

<sup>a</sup> For references see Table 16.5 in (1977AJ02).

For reaction (a) see (1971AJ02). Resonances observed in reactions (b, c, d) are displayed in Table 16.5 of (1982AJ01). Total cross sections for reaction (b) have been measured for  $0.2 \leq E_{\text{c.m.}} \leq 2.1$  MeV (1992BR05).

Proton groups have been observed to  $^{16}\text{N}$  states with  $E_x < 12$  MeV and angular distributions [with  $E(^3\text{He}) \leq 15$  MeV] lead to the  $J^\pi$  assignments shown in Table 16.8.

At  $E_\alpha = 46$  MeV the angular distributions of the groups to  $^{16}\text{N}^*(0.30, 3.96, 5.73, 7.60)$  have been determined: the most strongly populated state is the (5<sup>+</sup>) state  $^{16}\text{N}^*(5.73)$ . See (1971AJ02).

<sup>a</sup> For references see Table 16.7 in ([1982AJ01](#)).

<sup>b</sup>  $\tau_m = 5.1 \pm 0.3$  psec.

<sup>c</sup> The errors listed here for  $E_x$  for these two broad peaks are probably underestimates ([1986AJ04](#)).

<sup>d</sup> Results are ambiguous.

<sup>e</sup> May be a doublet.

<sup>f</sup> Identified with shell-model counterparts.

Observed proton groups are displayed in Table 16.9. See also ([1986AJ04](#)).

The thermal cross section is  $24 \pm 8 \mu\text{b}$ : see ([1981MUZQ](#)).

The scattering amplitude (bound)  $a = 6.44 \pm 0.03$  fm,  $\sigma_{\text{free}} = 4.59 \pm 0.05$  b,  $\sigma_{\text{inc}}$ <sup>spin</sup> (bound nucleus)  $< 1$  mb ([1979KO26](#)). The total cross section has been measured for  $E_n = 0.4$  to 32 MeV: see ([1977AJ02](#), [1981MUZQ](#)). Observed resonances are displayed in Table 16.10. See also ([1986AJ04](#), [1988MCZT](#), [1989FU1J](#)).

The activation cross section was measured for neutron energies between 14.6 and 15.0 MeV ([1986RO1C](#)).

<sup>a</sup> For references see Table 16.7 in (1977AJ02).

<sup>b</sup> Below  $E_{\text{n}} = 4.5$  MeV, the multilevel R-matrix formalism was used to determine  $E_{\lambda}$ ,  $\Gamma_{\lambda}$  and whenever possible  $J^{\pi}$  by a  $\chi^2$  fitting and minimization technique. Above this energy the  $2J + 1$  dependence was used; the parity cannot be determined because no marked interference effects are observed between resonance and potential scattering. Above 5.65 MeV all  $J$ -values are lower limits because the inelastic channel is open. [A channel radius  $a = 4.69$  fm was used.]

<sup>c</sup> Parity determined from angular distribution.

<sup>d</sup>  $J^{\pi}$  also obtained by phase-shift analysis.

<sup>e</sup> The phase-shift analysis indicates that the resonance is at  $E_{\text{n}} = 2.42 \pm 0.08$  MeV with  $\Gamma = 250 \pm 50$  keV. This is one of two ( $d_{3/2} p_{1/2}^{-1}$ ) single-particle resonances.

<sup>f</sup> The phase-shift analysis finds  $E_{\lambda} = 2.94 \pm 0.1$  MeV,  $\Gamma = 320 \pm 80$  keV.

This is the other ( $d_{3/2} p_{1/2}^{-1}$ ) single-particle resonance.

This reaction was studied with 200 MeV protons for  $E_{\text{x}} \leq 30$  MeV (1987AZZZ). A strong transition to a state with  $J^{\pi} = 5^+$  was observed at  $E_{\text{x}} = 5.7$  MeV. Strong states were also observed at  $E_{\text{x}} = 14.2$  and 16.1 MeV with cross sections falling sharply with angle.

Levels derived from observed proton groups and  $\gamma$ -rays are shown in Table 16.11. Gamma transitions are shown in the inset of fig. 2. The very strong evidence for  $J^\pi = 2^-, 0^-, 3^-$  and  $1^-$ , respectively for  $^{16}\text{N}^*(0, 0.12, 0.30, 0.40)$  is reviewed in (1971AJ02). These states provide a probe of the residual interaction relating the 1p and 2s 1d shells. See (1984BI03) for a comparison of experiment and theory for M1 observables. See also (1986AJ04, 1986ME1A, 1988VI1A).

See  $^{16}\text{C}$ .

Partial  $\mu^-$ -capture rates have been observed to  $^{16}\text{N}^*(0.12, 0.40)$  [ $J^\pi = 0^-, 1^-$ ] (1979GU06). The rate for capture by the  $J^\pi = 0^-$  state [“best” value:  $\lambda_\mu = 1560 \pm 94 \text{ sec}^{-1}$  (1985HE08)] and the “reverse” reaction  $^{16}\text{N}^*(0^-) \xrightarrow{\beta^-} {}^{16}\text{O}(0^+)$  [see Reaction 1] were the first reactions which verify the prediction (1978GU05, 1978GU07, 1978KU1A) of a large meson-exchange contribution to the weak, rank-zero axial charge. See  $^{16}\text{N}$ , Reaction 1 and (1981TO16, 1986NO04, 1990HA35, 1992WA1L). See also the measurement reported in (1990BL1H) and the calculation of (1990CH13).

Pion spectra have been obtained with virtual photons in the energy range  $E_\gamma = 200\text{--}350 \text{ MeV}$  (1987JE02). Cross sections corresponding to the population of the four lowest states of  $^{16}\text{N}$  (unresolved) were measured. Angular distributions were measured (1987YA02, 1987YA1D) at a photon energy of 320 MeV and the results compared to DWIA calculations. Measurements at  $E_e = 200 \text{ MeV}$  and  $E_{\pi^+} = 30 \text{ MeV}$  are cited in (1986AJ04).

At  $E_n = 59.6 \text{ MeV}$  differential cross sections for the protons to the first four states of  $^{16}\text{N}$  (unresolved) and to  $^{16}\text{N}^*(6.2, 7.8)$  have been analyzed by DWBA. Comparisons are made with results from the  $^{16}\text{O}(\gamma,\text{n})$  and  $^{16}\text{N}(\text{p},\gamma_0)$  reactions in the GDR region of  $^{16}\text{O}$  (1982NE04, 1984BR03). See also (1983SCZR, 1988NO1B, 1989BOYV). Other (n, p)-like charge exchange reactions are reviewed in (1989GA26), and data on ( $^{16}\text{O}$ ,  $^{16}\text{N}$ ) is presented in (1988HE1I).

Table 16.11: Levels of  $^{16}\text{N}$  from  $^{15}\text{N}(\text{d}, \text{p})$  and  $^{18}\text{O}(\text{d}, \alpha)$ <sup>a</sup>

<sup>a</sup> For the earlier references and additional information see Table 16.9 in (1982AJ01).

<sup>b</sup>  $^{15}\text{N}(\text{d}, \text{p})^{16}\text{N}$ .

<sup>c</sup>  $^{18}\text{O}(\text{d}, \alpha)^{16}\text{N}$ .

<sup>d</sup>  $\tau_m = 7.58 \pm 0.09$   $\mu\text{sec}$ .

<sup>e</sup>  $\tau_m = 131.7 \pm 1.9$  and  $5.63 \pm 0.05$  psec, respectively, for  $^{16}\text{N}^*(0.30, 0.40)$ ;  $|g| = 0.532 \pm 0.020$  for  $^{16}\text{N}^*(0.30)$  (1984BI03).

<sup>f</sup>  $\Gamma$  for this level and the ones listed below  $\leq 40 - 50$  keV.

<sup>g</sup> These levels appear to be correlated with thresholds for neutron emission to excited states of  $^{15}\text{N}$ .

<sup>h</sup> (1982MA25):  $E_d = 52$  MeV.

<sup>i</sup> A closely spaced doublet appears to be present. At least one of the states has unnatural parity.

At  $E_t = 23.5$  MeV  $^{16}\text{N}^*(0, 0.30)$  [ $J^\pi = 2^-, 3^-$ ] are strongly populated relative to  $^{16}\text{N}^*(0.12, 0.40)$  [ $J^\pi = 0^-, 1^-$ ]: see (1982AJ01). See also (1988CL04).

Measurements at  $E({}^7\text{Li}) = 50$  MeV to  $^{16}\text{N}^*(0, 0.12, 0.30, 0.40, 3.35, 3.52, 3.96, 5.52, 5.73, 6.17)$  are reviewed in (1986AJ04). A microscopic DWBA Coupled-Channels analysis of data at  $E({}^7\text{Li}) = 50$  MeV is reported in (1986CL03). See also the review of charge-exchange reactions with  ${}^7\text{Li}$  ions in (1989GA26).

Bremsstrahlung-weighted integrated cross sections have been measured (1989OR07). About 90% of the photoproton emission populates the ground state ( $2^-$ ) and the 0.298 MeV ( $3^-$ ) levels. The 0.120 MeV ( $0^-$ ) and 0.397 MeV ( $1^-$ ) levels are also populated. See also (1986OR1A). Measurements with quasimonoenergetic photons at  $E_\gamma = 13.50\text{--}43.15$  MeV were carried out by (1992ZU01) to study the GDR in  $^{17}\text{O}$ .

See Table 16.10 in (1982AJ01).

Coincidence measurements for  $E_\pi = 116$  MeV,  $\theta_{\text{p}_1} = 50^\circ$ ,  $\theta_{\text{p}_2}$  variable have been reported by (1986SC28, 1986SCZX). Transitions to the unresolved cluster of 4 states below 0.4 MeV excitation were observed to account for  $6.1 \pm 0.6\%$  of the estimated two-nucleon absorption cross section below 20 MeV excitation. The results were compared with a model of pion absorption on quasi-deuteron pairs.

At  $E_p = 43$  MeV, the angular distribution of the  $^3\text{He}$  nuclei corresponding to a state at  $E_x = 9.9$  MeV fixes  $L = 0$  and therefore  $J^\pi = 0^+$  for  $^{16}\text{N}^*(9.9)$ : it is presumably the  $T = 2$  analog of the ground state of  $^{16}\text{C}$ . See (1982AJ01, 1986AJ04). See also (1985BLZY).

Alpha particle groups observed in this reaction are displayed in Table 16.11. For polarization studies see (1982AJ01) and  $^{20}\text{F}$  in (1983AJ01, 1987AJ02).  $\tau_m$  for  $^{16}\text{N}^*(0.40) = 6.5 \pm 0.5$  psec and  $|g| = 1.83 \pm 0.13$ : see (1982AJ01).

See (1982AJ01) and  $^{20}\text{F}$  in (1983AJ01).

**<sup>16</sup>O**  
 (Figs. 3 and 5)

GENERAL: See Table 16.12.

$$\langle r^2 \rangle^{1/2} = 2.710 \pm 0.015 \text{ fm } (\textcolor{red}{1978\text{KI01}})$$

$$\text{Abundance} = (99.762 \pm 0.015)\% \text{ } (\textcolor{red}{1984\text{DE53}})$$

$$|g| = 0.556 \pm 0.004 \text{ } (\textcolor{red}{1984\text{AS03}})$$

Total reaction cross sections and characteristic  $\gamma$ -ray cross sections for  ${}^9\text{Be} + {}^9\text{Be}$  were measured for  $E_{\text{c.m.}} = 1.4\text{--}3.4 \text{ MeV}$  ([1988LA25](#)). Gamma rays were observed from levels at  $6.13$  ( $3^-$ ),  $6.917$  ( $2^+$ ), and  $7.1117$  ( $1^-$ ) MeV populated by the  ${}^9\text{Be}({}^9\text{Be}, 2\text{n}){}^{16}\text{O}$  reaction. Cross sections calculated with optical models agreed with elastic scattering data, but the total reaction cross section was underpredicted by a factor of 2 to 3.

Energy spectra of the  ${}^{16}\text{O}$  nuclei were measured ([1986BE35](#)) for incident  ${}^{11}\text{B}$  energies of 88 MeV to obtain information on the  ${}^4\text{He}$  system.

This reaction was studied by ([1988BEYJ](#)).

	Complex Reactions – continued
<b>1988AN1C</b>	Multiple angular scattering of $^{16,17}\text{O}$ , $^{40}\text{Ar}$ , $^{86}\text{Kr}$ and $^{100}\text{Mo}$ at 20–90 MeV/u
<b>1988AR1D</b>	Interactions of 60 & 200 A GeV $^{16}\text{O}$ ions in nuclear emulsion
<b>1988AY03</b>	Transport description for capture processes in nuclear collisions
<b>1988BO13</b>	Deeply inelastic collisions as a source of intermediate mass fragments at $E/A = 27$ MeV
<b>1988BR1N</b>	Fragmentation cross sections of $^{16}\text{O}$ at 60 & 200 GeV/nucleon
<b>1988CA27</b>	Experimental indications of selective excitations in dissipative heavy ion collisions
<b>1988FE1A</b>	Meas. C, O, & Fe charge changing $\sigma$ in He & H at high $E$ ; appl. to cosmic-ray propag.
<b>1988GA11</b>	Neutron pickup & 4-body processes in reactions of $^{16}\text{O} + ^{197}\text{Au}$ at 26.5 & 32.5 MeV/u
<b>1988GA12</b>	Stripping- & pickup-induced breakup in 11- & 17-MeV/u $^{20}\text{Ne} + ^{197}\text{Au}$ reactions
<b>1988GO11</b>	Emissions of complex frags. & effective temps. for collisions of $^{58}\text{Ni} + ^{58}\text{Ni}$ at 11 MeV
<b>1988HA03</b>	Spin dependence of neutron transfer in heavy ion reactions
<b>1988KH1B</b>	Excit.-decay vs. fragment production for $^{12}\text{C}(^{16}\text{O}, ^{15}\text{N} + \text{p})$ ; $E = 1.05$ & 2.1 A GeV (A)
<b>1988MI28</b>	Multifragmentation as a possible signature of liquid-gas phase transitions
<b>1988MO05</b>	Dynamical model for projectile break-up & incomplete fusion in $^{20}\text{Ne} + ^{197}\text{Au}$
<b>1988POZZ</b>	Multifragmentation of the projectiles $^{16}\text{O}$ , $^{14}\text{N}$ , and $^{12}\text{C}$ at 32.5 MeV/A (A)
<b>1988SH03</b>	$^{28}\text{Si} + ^{14}\text{N}$ orbiting interaction (experimental data) & importance of phase space
<b>1988SH1H</b>	Coincidence meas. between $\alpha$ -particles & projectile-like frags. in 82.7 MeV $^{16}\text{O} + ^{27}\text{Al}$
<b>1988SI01</b>	Fragmentation of $^{16}\text{O}$ projectiles at 100 MeV/nucleon
<b>1988TE03</b>	Incomplete deep-inelastic scattering in $^{20}\text{Ne} + ^{197}\text{Au}$ collisions at 20 MeV/nucleon
<b>1988UT02</b>	Quasi-free stripping mechanism of Serber model extended to complex projectiles
<b>1988WI1F</b>	Electromagnetic spallation of 3.2 TeV $^{16}\text{O}$ nuclei (A)
<b>1989AD1B</b>	Production of He projectile fragments in $^{16}\text{O}$ -emulsion interactions at $E/A = 2$ –200 GeV
<b>1989BR14</b>	Dynam. anal. of deep inelas. interac. in $^{19}\text{F} + ^{24}\text{Mg}$ at 1.3 MeV/u above Coulomb barrier
<b>1989CA15</b>	Fusion & binary reactions in the collision of $^{32}\text{S}$ on $^{26}\text{Mg}$ at $E_{\text{lab}} = 163.5$ MeV
<b>1989FI05</b>	Non-eq. vs. equilibrium complex. frag. emiss.; $^{14}\text{N} + \text{Ag}$ & $^{14}\text{N} + \text{Au}$ at $E/A = 20$ –50 MeV
<b>1989GE11</b>	Complex fragments emitted in excited states
<b>1989GR13</b>	Compound nucleus emission of intermediate mass fragments in $^6\text{Li} + \text{Ag}$ at 156 MeV
<b>1989MA45</b>	Target excitation & angular momentum transfer in $^{28}\text{Si} + ^{181}\text{Ta}$ from multiplicity meas.
<b>1989PO06</b>	Approach to criticality in the fragmentation of Xe by 1–19 GeV protons
<b>1989PO07</b>	Excitation & multiple dissociation of $^{16}\text{O}$ , $^{14}\text{N}$ , and $^{12}\text{C}$ projectiles at 32.5 MeV/u
<b>1989RE08</b>	Large transient magnetic fields for single electron O ions on a 10 fs time scale (O + Gd)
<b>1989SA10</b>	Total cross sections of reactions induced by neutron-rich light nuclei
<b>1989TE02</b>	Dissipative mechanisms in the 120 MeV $^{19}\text{F} + ^{64}\text{Ni}$ reaction
<b>1989YO02</b>	Quasi-elastic & deep inelastic transfer in $^{16}\text{O} + ^{197}\text{Au}$ for $E < 10$ MeV/u
<b>1989YO09</b>	Energy damping feature in light heavy-ion reactions (including 118 MeV $^{16}\text{O} + ^{48}\text{Ti}$ )
<b>1989ZHYZ</b>	Mass measurement of $Z = 7$ –19 neutron-rich nuclei using the TOFI spectrometer (A)
<b>1990BO01</b>	Critical excitation energy in fusion-evaporation reactions

- Complex Reactions – continued
- 
- 1988AN1C** Multiple angular scattering of  $^{16,17}\text{O}$ ,  $^{40}\text{Ar}$ ,  $^{86}\text{Kr}$  and  $^{100}\text{Mo}$  at 20–90 MeV/u
- 1988AR1D** Interactions of 60 & 200 A GeV  $^{16}\text{O}$  ions in nuclear emulsion

		7.12	$1^-; 0$	$3.1 \pm 0.8$	$1.4 \pm 0.4$

<sup>a</sup> See Tables 16.12 in (1971AJ02), 16.15 in (1977AJ02) and 16.12 in (1982AJ01) for the earlier work and for references. See also Table 16.15 here.

<sup>b</sup> Monopole matrix element in fm<sup>2</sup>.

<sup>c</sup> Weighted mean of earlier measurements and of a newer one reported in reaction 42 (1985MO10).

<sup>d</sup>  $(3.0 \pm 0.4) \times 10^{-4}$  [M1],  $(2.5 \pm 0.2) \times 10^{-3}$  [E2] (1982VE04).

<sup>e</sup>  $(8 \pm 3) \times 10^{-5}$  [M1],  $(3.4 \pm 0.5) \times 10^{-4}$  [E2] (1982VE04).

<sup>f</sup>  $E_\gamma = 2471.5 \pm 0.5$  keV for  $(8.87 \rightarrow 6.13)$  transition.

<sup>g</sup> Pairs due to this transition are not observed.

<sup>h</sup> For the radiative decay of higher states see Tables 16.15, 16.22, and 16.26.

<sup>i</sup> (1982VE04). See also for  $\delta$ .

<sup>j</sup> (1986ZI08).

At  $E(^6\text{Li}) = 4.9$  MeV, the cross sections for reactions (b) to (f) leading to low-lying states in the residual nuclei are proportional to  $2J_f + 1$ : this is interpreted as indicating that the reactions proceed via a statistical compound nucleus mechanism. For highly excited states, the cross section is higher than would be predicted by a  $2J_f + 1$  dependence: see (1982AJ01, 1986AJ04).

States of  $^{16}\text{O}$  observed at  $E(^{10}\text{B}) = 20$  MeV are displayed in Table 16.10 of (1977AJ02). At the higher excitation energies, states are reported at  $E_x = 17.200 \pm 0.020$ ,  $17.825 \pm 0.025$ ,  $18.531 \pm 0.025$ ,  $18.69 \pm 0.03$ ,  $18.90 \pm 0.035$ ,  $19.55 \pm 0.035$ ,  $19.91 \pm 0.02$ ,  $20.538 \pm 0.015$ ,  $21.175 \pm 0.015$ ,  $21.84 \pm 0.025$ ,  $22.65 \pm 0.03$  and  $23.51 \pm 0.03$  MeV. The reaction excites known  $T = 0$  states:  $\sigma_t$  follows  $2J_f + 1$  for 11 of 12 groups leading to states of known  $J$ . The angular distributions show little structure: see (1977AJ02).

Cross section measurements at  $E_{\text{c.m.}} = 1.46\text{--}6.10$  MeV were reported in (1990DA03).

<sup>a</sup> References are listed in Tables 16.11 ([1971AJ02](#)), 16.12 ([1977AJ02](#)), 16.13 ([1982AJ01](#)), and 16.12 ([1986AJ04](#)).

<sup>b</sup>  $p_0$  corresponds to  $^{15}\text{N}(0)$ .  $\alpha_0$ ,  $\alpha_1$  corresponds to  $^{12}\text{C}^*(0, 4.4)$  and  $\gamma_{4.4}$  corresponds to the  $\gamma$ -ray from the decay of  $^{12}\text{C}^*(4.4)$ ;  $\gamma_0, \gamma_1, \gamma_2, \gamma_3, \gamma_4$  correspond to the transitions to  $^{16}\text{O}^*(0, 6.05, 6.13, 6.92, 7.12)$ .

<sup>c</sup> These are observed widths from ([1987RE02](#)). We are indebted to Dr. F.C. Barker who informed us of these and other recent observed width determinations.  $\Gamma_{\gamma_3}^0 = 2.4 \pm 1.4$  meV ([1987RE02](#)),  $\Gamma_{\gamma_3} = 2.4$  meV,  $\Gamma_{\gamma_4} = 8.0$  meV ([1991BA1K](#)),  $\Gamma_{\gamma_0} = 16.4$  meV (*R*-matrix fit by ([1991HU10](#))).

<sup>d</sup> Branching ratios to  $^{16}\text{O}^*(0, 6.05) = 98.8\%, 1.2\%$ .

<sup>e</sup>  $\Gamma_{\gamma_0} = 0.7 \pm 0.2$  eV, based on  $\Gamma_{\alpha_0}/\Gamma = 1.0$  and  $\Gamma_{\text{c.m.}} = 190 \pm 40$  keV.

<sup>f</sup>  $\Gamma_{\alpha_0}\Gamma_{\gamma_0}/\Gamma^2 = (1.49 \pm 0.17) \times 10^{-4}$ .

<sup>g</sup> Uncertainties in  $E_x$  may be larger.

<sup>h</sup> For this and the states below  $\Gamma_\alpha/\Gamma$  is  $\pm 0.10$  for isolated narrow levels.

<sup>i</sup>  $\Gamma_{\alpha_2}/\Gamma = 0.16$  ([1982KA30](#)).

<sup>j</sup> A resonance is reported at  $E_\alpha = 19.4$  MeV:  $4^+$  is dominant,  $\Gamma_\alpha/\Gamma \ll 1$ ,  $\Gamma \geq 0.48$  ([1982KA30](#)).

<sup>k</sup>  $\Gamma_{^8\text{Be}}$ ,  $\Gamma_{\alpha_0}$ , and  $\Gamma_{\alpha_2} \approx 3.5, 1.5 \pm 0.5$  and  $\approx 6$  keV, respectively.

<sup>l</sup>  $\Gamma_{\alpha_2}/\Gamma = 0.2$  ([1983AR12](#)).

<sup>m</sup> Broad maxima are reported in the activation cross section at  $E_\alpha = 22.8, 24.3, 25.3$  and  $26.9$  MeV ([1983KOZD](#); prelim.).

<sup>n</sup> See ([1981SA07](#)) for  $(\alpha, \gamma_{14.8})$  measurements which indicate an  $8^+$  GQR built on the  $6_1^+$  state  $^{16}\text{O}^*(14.82)$ .

<sup>b</sup> 3-level R fitting.

<sup>c</sup> Hybrid R fitting.

<sup>d</sup> K fitting.

The yield of capture  $\gamma$ -rays has been studied for  $E_\alpha$  up to 42 MeV [see Table 16.11 in (1977AJ02) and (1982AJ01)]. See also (1986AJ04). Observed resonances are displayed in Table 16.15 here.

This reaction plays an important role in astrophysical processes. The cross sections at astrophysical energies have been obtained by fitting measured cross sections and extrapolating them to low energies utilizing standard R-matrix, Hybrid R-matrix and K-matrix procedures. A list of recent values of the E2 and E1 astrophysical factors for  $E_0 = 300$  keV obtained from fits to the data is given in Table 16.16.

The influence of vacuum polarization effects on subbarrier fusion is evaluated in (1988AS03), and the relevance of Coulomb dissociation of  $^{16}\text{O}$  into  $^{12}\text{C} + \alpha$  is studied in (1986BA50, 1989BA64, 1992SH11). Calculations to test the sensitivity of stellar nucleosynthesis to the level in  $^{12}\text{C}$  at 7.74 MeV are described in (1989LI29). For other astrophysical studies see (1982AJ01, 1986AJ04) and (1985TA1A, 1986FI15, 1986MA1E, 1986WO1A, 1987AR1C, 1987BO1B, 1987DE32, 1987RO25, 1988CA26, 1988PA1H, 1988TRZZ, 1990BL1K, 1990BR1Q, 1990JI02).

At higher energies the E2 cross section shows resonances at  $E_x = 13.2, 15.9, 16.5, 18.3, 20.0$ , and 26.5 MeV [see Table 16.16]. Some E2 strength is also observed for  $E_x = 14$  to 15.5 and 20.5 to 23 MeV. In the range  $E_\alpha = 7$  to 27.5 MeV the  $T = 0$  E2 strength is  $\sim 17\%$  of the sum-rule value. It appears from this and other experiments that the E2 centroid is at  $E_x \sim 15$  MeV, with a 15 MeV spread. Structures are observed in the yield of  $\gamma$ -rays from the decay to  $^{16}\text{O}^*(14.8 \pm 0.1)$ .

for  $E_x = 34\text{--}39$  MeV. It is suggested that these correspond to a giant quadrupole excitation with  $J^\pi = 8^+$  built on the  $6_1^+$  state at  $E_x = 14.815$  MeV: see ([1982AJ01](#), [1986AJ04](#)).

8. (a) $^{12}\text{C}(\alpha, \text{n})^{15}\text{O}$	$Q_m = -8.502$	$E_b = 7.161$
(b) $^{12}\text{C}(\alpha, \text{p})^{15}\text{N}$	$Q_m = -4.966$	
(c) $^{12}\text{C}(\alpha, \text{d})^{14}\text{N}$	$Q_m = -13.575$	

For reaction (a) cross section measurements from threshold to  $E_\alpha = 24.7$  MeV [see ([1986AJ04](#))], and at  $E_\alpha = 10.5$  to 20 MeV (see Table [16.16](#) here). For excitation functions from  $E_\alpha = 21.8$  to 27.2 MeV, see ([1986AJ04](#)). Thick-target neutron yields have been measured for  $E_\alpha = 1.0$  to 9.8 MeV ([1989HE04](#)) and for 4–7 MeV ([1982WE16](#)). For reaction (b) cross section measurements from threshold to 33 MeV, see ([1986AJ04](#)). The excitation curve for  $p_3$  (to  $^{15}\text{N}^*(6.32)$ ), measured for  $E_\alpha = 24$  to 33 MeV, shows a large peak at  $E_x \approx 29$  MeV,  $\Gamma \approx 4$  MeV. It is suggested that it is related to the GQR in  $^{16}\text{O}$ : see ([1982AJ01](#)). For reaction (c) deuteron spectra have been measured for  $E_\alpha = 200, 400, 600, 800$  MeV/nucleon ([1991MO1B](#)). For the observed resonances see Table [16.16](#) here.

The yield of  $\alpha$ -particles leading to  $^{12}\text{C}^*(0, 4.4, 7.7)$  and 4.4, 12.7 and 15.1 MeV  $\gamma$ -rays has been studied at many energies in the range  $E_\alpha = 2.5$  to 42 MeV [see ([1986AJ04](#))], and at  $E_\alpha = 0.4\text{--}1.8$  MeV ([1990TO09](#)). Observed resonances are displayed in Table [16.15](#). Attempts have been made to observe narrow states near  $^{16}\text{O}^*(8.87, 9.85)$ . No evidence has been found for a narrow (100 eV)  $0^+$  state in the vicinity of the  $2^-$  state at 8.87 MeV [see ([1982AJ01](#))] nor for a  $3^-$  state near the  $2^+$  state at 9.84 MeV ([1986AJ04](#)).

For total cross section measurements see ([1986AJ04](#)) and for  $E_\alpha = 100$  MeV ([1986DU15](#)). For integral cross sections for inelastic scattering at 50.5 MeV, see ([1987BU27](#)). For elastic scattering differential cross sections at  $E_\alpha = 96.6$  MeV see ([1990KO2C](#)), at 90 MeV ([1990GL02](#)), at 90 and 98 MeV ([1991GO25](#)). For diffraction scattering at momentum 17.9 GeV/c, see ([1991AB1F](#)). For inelastic scattering and polarization of  $^{12}\text{C}$  (9.64 MeV,  $3^-$ ) see ([1989KO55](#), [1991KO40](#)), who report that the reaction at  $E_\alpha = 27.2$  MeV proceeds mostly via an  $8^+$  state in the compound system. For pion production at momenta 4.5 GeV/c per nucleon see ([1990AB1D](#)), at 4.2 GeV/c per nucleon ([1987AG1A](#)), at energies of 3.6 GeV per nucleon ([1987AN20](#)), and at 200 to 800 MeV per nucleon ([1987LH01](#)), at  $E_\alpha = 0.8, 1.6$  GeV ([1991LE06](#)). Differential cross sections at  $E_\alpha = 1\text{--}6.6$  MeV measured to obtain information on  $^{12}\text{C}(\alpha, \gamma)$  stellar reaction rates are reported by ([1987PL03](#)).

Calculations of total cross sections for  $E_\alpha = 96.6\text{--}172.5$  MeV are presented in ([1989KU30](#)) and distributions of  $\alpha$ -particle strengths in ([1988LE05](#)). Energy dependence at high energies ( $\sim 1$  GeV/nucleon) is studied in ([1988MO18](#)). The iterative-perturbative method for S-matrix to potential inversion was applied to  $\alpha + ^{12}\text{C}$  phase shifts at  $E_{\text{lab}} = 1.0\text{--}6.6$  MeV in ([1990CO29](#)). See

also (1991LI25). Nucleus-nucleus scattering and interaction radii were studied in (1986SA30). Core-plus alpha particle states in  $^{16}\text{O}$  populated in  $\alpha + ^{12}\text{C}$  scattering are studied in terms of vibron models in (1988CS01). See also (1991AB10, 1991DE15, 1991ES1B, 1991RU1B, 1992SA26). The effects of electron screening on low energy fusion reactions of astrophysical interest are explored in (1987AS05, 1990TO09). The nature of the  $\alpha + ^{12}\text{C}$  potential at low energy is explored in (1990AL05). For other theoretical work see (1986MI24, 1986SU06, 1987BA83, 1989BA92, 1990DA1Q).

10. (a) $^{12}\text{C}(\alpha, ^8\text{Be})^8\text{Be}$	$Q_m = -7.4585$	$E_b = 7.16195$
(b) $^{12}\text{C}(\alpha, 2\alpha)^8\text{Be}$	$Q_m = -7.365$	

The yield of  $^8\text{Be}$  from reaction (a) shows a number of resonances: see Table 16.16. There is no evidence below  $E_x \sim 24$  MeV for  $J^\pi = 8^+$  states although the existence of such states below this energy cannot be ruled out since it is possible that the  $L$  of the entrance channel inhibits the formation of such states. Above 26 MeV  $L = 8$  becomes dominant: see (1982AJ01, 1986AJ04). See also the angular distribution measurements of (1991GL03) at  $E_\alpha = 90$  MeV. For differential cross sections for reaction (b) at  $E_\alpha = 27.2$  MeV see (1987KO1E). See also (1977AJ02).

11. $^{12}\text{C}(^6\text{Li}, \text{d})^{16}\text{O}$	$Q_m = 5.6868$
---	----------------

This reaction has been studied at many energies: see (1977AJ02) and Table 16.17 here. At higher energies the spectra are dominated by states with  $J \geq 4$  and natural parity (1986AJ04). A kinematic coincidence technique was applied in (1986CA19) to study the unresolved doublet at  $E_x = 11.09$  MeV enabling clear observation of the  $\gamma$ -decaying  $3^+$  member at 11.080 MeV although it contributes only  $\sim 15\%$  of the singles yield of the doublet which is dominated by the  $4^+$  member at 11.096 MeV. Angular correlation measurements (1980CU08) suggested that the 11.096  $4^+$  state is populated via a two-step process, and this interpretation was confirmed in calculations by (1988SE07). See also (1986AJ04). An interference effect was observed in the angular correlation function for the  $7^-$  level at  $E_x = 20.9$  MeV in measurements by (1987AR28). See also (1986AR1A, 1987BE1C, 1987GO1C, 1988ARZU).

Inclusive deuteron spectra from the break-up of  $^6\text{Li}$  ions at 156 MeV are described in (1989JE07). See also (1986AJ04).

A numerical method for evaluation of  $(^6\text{Li}, \text{d})$  stripping into the  $5^-$  (15.6 MeV) and  $6^+$  (16.3 MeV) states is presented in (1989SE06). See also (1991SE12). An extensive discussion of alpha clustering in nuclei is presented in (1990HO1Q). Cluster stripping and heavy-group substitution in the reaction is discussed in (1988BE49), and the effect of including Coulomb forces in the Faddeev formalism is studied in (1988OS05).

Table 16.17: States of  $^{16}\text{O}$  from  $^{12}\text{C}(^{6}\text{Li}, \text{d})$  and  $^{12}\text{C}(^{7}\text{Li}, \text{t})$ 

$E_x^a$ (MeV $\pm$ keV)	$\Gamma_{\text{c.m.}}^b$ (keV)	$\theta_\alpha^2/\theta_\alpha^2(2^+)^c$	$\Gamma_{\alpha_0}/\Gamma$	$J^\pi; K^\pi$

$23.8 \pm 100$	$1980 \pm 250$			$(6^+)$
$26.9 \pm 100$	$1700 \pm 250$			$(7^-)$
27.7 <sup>f</sup>				$(7^-)$
(29.3) <sup>f</sup>				$(7^-)$
32 <sup>g</sup>	broad			
34 <sup>h</sup>				$10^+(9^-)$
35 <sup>g</sup>	broad			

<sup>a</sup>  $E_x$  quoted without errors are from Table 16.13. For the earlier references see Table 16.14 ([1982AJ01](#)). Angular distributions are reported in both reactions for the first nine states.

<sup>b</sup> Line widths, not corrected for  $\alpha$ -penetrabilities.

<sup>c</sup> Ratio of dimensionless reduced  $\alpha$ -width calculated at a channel radius of 5.4 fm, relative to that for  $^{16}\text{O}^*(6.92)$ . (N, L) here are taken to be (2, 0) and (4, 1) respectively, for  $^{16}\text{O}^*(0, 7.12)$ . The first number listed is the value reported at  $E(^6\text{Li}) = 42$  MeV, the second at  $E(^6\text{Li}) = 90.2$  MeV.

<sup>d</sup> On the basis of studies of the  $^{12}\text{C}(^6\text{Li}, \text{d})$ ,  $^{12}\text{C}(^7\text{Li}, \text{t})$ ,  $^{12}\text{C}(^{10}\text{B}, ^6\text{Li})$  and  $^{19}\text{F}(\text{p}, \alpha)$  reactions, the energy of  $^{16}\text{O}^*(9.6)$  is  $9619 \pm 15$  keV with  $\Gamma = 400 \pm 100$  keV (line width).  $\Gamma_R = 430 \pm 10$  keV as inferred from the best fit B-W line shape. This value is corrected for penetrability ([1981OV02](#); Beccetti, private communication.).

<sup>e</sup> Angular distributions are reported at  $E(^6\text{Li}) = 35.5 - 35.6$  MeV to  $^{16}\text{O}^*(10.36)$  and to the unresolved  $3^+$  and  $4^+$  states at 11.1 MeV ([1986AJ04](#)). More recent coincidence measurements ([1986CA19](#)) have indicated that while the  $4^+$  state is dominantly populated and decays by  $\alpha$  emission, the  $3^+$  state decays by  $\gamma$  emission. Angular correlation measurements ([1980CU08](#)) and analysis ([1988SE07](#)) indicate the the  $4^+$  state is populated by a two-step process.

<sup>f</sup> ([1982AR20](#)); decay primarily by  $\alpha_0$ .

<sup>g</sup> ([1982AR20](#)); decay primarily by  $\alpha_1$ .

<sup>h</sup> ([1982AR20](#), [1983AR12](#)); decays primarily by  $\alpha_2$ .

This reaction has been studied extensively: see ([1977AJ02](#), [1982AJ01](#)) and Table 16.17 here. Measurements of  $\alpha$ -t angular correlations for the process  $^{12}\text{C}(^7\text{Li}, \text{t})^{16}\text{O}(\alpha)^{12}\text{C}$  are reported in ([1988AR22](#)) for the  $7^-$  (20.9 MeV),  $6^+$  (16.3 MeV), and  $5^-$  (14.6 MeV) levels in  $^{16}\text{O}$ . Analyses of the ( $^7\text{Li}, \text{t}$ ) reaction for cluster states in  $^{16}\text{O}$  are reported in ([1986CO15](#), [1988BE49](#)). See also ([1987BE1C](#), [1988BE1D](#), [1988BEYB](#), [1989AL1D](#), [1990HO1Q](#)) and the sections on  $^{19}\text{F}$  in ([1983AJ01](#), [1987AJ02](#)).

Angular distributions at  $E(^{10}\text{B}) = 18$  and 45 MeV have been studied involving  $^{16}\text{O}^*(0, 6.1, 7.1, 8.9, 9.9, 10.4)$ . At  $E(^{10}\text{B}) = 68$  MeV angular distributions to  $^{16}\text{O}^*(0, 6.1, 6.9, 10.4, 11.1, 14.7, 16.2, 20.9)$  are forward peaked and fairly structureless.  $^{16}\text{O}^*(0, 6.9, 11.1)$  are weakly excited: see ([1982AJ01](#), [1986AJ04](#), [1990HO1Q](#)).

Angular distributions have been reported at  $E(^{12}\text{C})$  to 63 MeV [see (1977AJ02)] and at 4.9 to 10.5 MeV, and 11.2 to 12.6 MeV [see (1986AJ04)]. Angular correlations at  $E(^{12}\text{C}) = 78$  MeV confirm  $J^\pi = 4^+, 5^-, 6^+$  and  $7^-$  for  $^{16}\text{O}^*(10.36, 14.59, 16.3, 20.9)$ .  $\Gamma_{\gamma_0}/\Gamma = 0.90 \pm 0.10$ ,  $0.75 \pm 0.15$  and  $0.90 \pm 0.10$ , respectively, for the first three of these states. In addition a state is reported at  $E_x = 22.5 \pm 0.5$  MeV which may be the  $8^+$  member of the  $K^\pi = 0^+$ , 4p-4h rotational band (1979SA29). For further work at  $E(^{12}\text{C}) = 90, 110$  and  $140$  MeV see (1986SH10). At  $E(^{12}\text{C}) = 120$  MeV  $\alpha_0$  decays of  $^{16}\text{O}^*(16.3, 20.9)$  [ $J^\pi = 6^+, 7^-$ ] and  $\alpha_1$  decays of  $^{16}\text{O}^*(19.1, 22.1, 23.5)$  are observed as is a broad structure in both channels corresponding to  $^{16}\text{O}^*(30.0)$  with  $J^\pi = 9^- + 8^+$ . A gross structure  $^{12}\text{C}$ - $^{12}\text{C}$  resonance at  $E_{\text{c.m.}} = 25$  MeV in the reaction leading to the  $^{16}\text{O}$  11.09 MeV  $4^+$  state is reported in (1987RA22). For other work on alpha cluster resonances see (1986ALZN, 1986RAZI, 1987RA02, 1990HO1Q). Measurements of differential cross sections at sub-barrier energies  $2.43 \leq E_{\text{c.m.}} \leq 5.24$  MeV are reported in (1989CU03) and a statistical model calculation is discussed in (1990KH05). See also (1991CE09). For the decay of  $^{20}\text{Ne}$  states see (1983AJ01, 1986AJ04, 1987AJ02), and for excitation functions see (1986AJ04).

15. (a) $^{12}\text{C}(^{14}\text{N}, ^{10}\text{B})^{16}\text{O}$	$Q_m = -4.4503$
(b) $^{12}\text{C}(^{17}\text{O}, ^{13}\text{C})^{16}\text{O}$	$Q_m = 0.8027$

Angular distributions are reported at  $E(^{14}\text{N}) = 53$  MeV involving  $^{16}\text{O}^*(0, 6.05, 6.13, 6.92)$  and various states of  $^{10}\text{B}$ , and at 78.8 MeV involving  $^{16}\text{O}_{\text{g.s.}}$ : see (1982AJ01). Angular distributions have been measured for the g.s. in reaction (b) for  $E(^{17}\text{O}) = 40$  to  $70$  MeV (1986AJ04). See also (1986AR04, 1989WUZZ, 1990HO1Q), the two-center shell model basis calculations of (1991TH04) and the review of Landau-Zener effect investigations in (1990TH1D).

16. $^{12}\text{C}(^{20}\text{Ne}, ^{16}\text{O})^{16}\text{O}$	$Q_m = 2.428$
---	---------------

Angular distributions have been measured to  $E(^{20}\text{Ne}) = 147$  MeV: see (1977AJ02). For yield measurements see (1986AJ04). Studies of projectile-breakup and transfer re-emission in the  $^{12}\text{C} + ^{20}\text{Ne}$  system at an incident  $^{20}\text{Ne}$  energy of 157 MeV are described in (1987SI06). See also (1990HO1Q).

17. (a) $^{13}\text{C}(^3\text{He}, \gamma)^{16}\text{O}$	$Q_m = 22.79338$

(e) $^{13}\text{C}(^3\text{He}, ^3\text{He})^{13}\text{C}$	
(f) $^{13}\text{C}(^3\text{He}, \alpha)^{12}\text{C}$	$Q_m = 15.6314$
(g) $^{13}\text{C}(^3\text{He}, ^8\text{Be})^{8}\text{Be}$	$Q_m = 8.1729$

The yield of capture  $\gamma$ -rays (reaction a) has been studied for  $E(^3\text{He})$  up to 16 MeV [see (1977AJ02)], as have angular distributions. Observed resonances are displayed in Table 16.18. It is suggested that the structures at  $E_x \approx 26$ –29 MeV are related to the giant resonances built on the first few excited states of  $^{16}\text{O}$  (1979VE02). See also (1986AJ04).

The excitation functions (reaction b) up to  $E(^3\text{He}) = 11$  MeV are marked at low energies by complex structures and possibly by two resonances at  $E(^3\text{He}) = 1.55$  and 2.0 MeV: see Table 16.18. See also (1977AJ02) for polarization measurements. Excitation functions (reaction c) for  $E(^3\text{He}) = 3.6$  to 6.6 MeV have been measured for  $p_0, p_{1+2}, p_3$ : a resonance is reported at  $E(^3\text{He}) = 4.6$  MeV. A resonance at 6 MeV has also been observed: see Table 16.18. A comparison of polarization measured in this reaction and of analyzing powers measured in  $^{15}\text{N}(p, ^3\text{He})$  has been made [see (1986AJ04)]. Analyzing powers have been measured at  $E(^3\text{He}) = 33$  MeV for the elastic scattering (reaction d) and the deuteron groups to  $^{14}\text{N}^*(0, 2.31, 3.95, 9.51)$  (1986DR03).

Yields of  $\alpha_0, \alpha_1, \alpha_2$ , and  $\gamma$ -rays from the decay of  $^{12}\text{C}^*(12.71, 15.11)$  (reaction f) have been studied up to  $E(^3\text{He}) = 12$  MeV. Observed resonances are displayed in Table 16.18. Those seen in the yield of  $\gamma_{15.1}$  are assumed to correspond to  $^{16}\text{O}$  states which have primarily a  $T = 1$  character. Analyzing power measurements are reported at  $E(^3\text{He}) = 33$  MeV to  $^{12}\text{C}^*(4.4)$ . Excitation functions for  $\alpha_0$  and  $\alpha_1$  are also reported for  $E(^3\text{He}) = 16$  to 23 MeV (1986AJ04). DWBA analyses for data at  $E(^3\text{He}) = 50, 60$  MeV are described in (1990ADZU). See also (1986ZE1B). The excitation function for  $^8\text{Be}(\text{g.s.})$  (reaction g) has been studied for  $E(^3\text{He}) = 2$  to 6 MeV. It shows a strong resonance at  $E(^3\text{He}) = 5.6$  MeV corresponding to a state in  $^{16}\text{O}$  at  $E_x = 27.3$  MeV.  $J^\pi$  appears to be  $2^+$  from angular distribution measurements. A search for anomalous deuterons at 10.8 GeV has been reported (1986AJ04).

Angular distributions for the  $n_0$  group have been measured for  $E_\alpha = 12.8$  to 22.5 MeV: see (1971AJ02). Polarization measurements for  $n_0$  at  $\theta = 0$ –70° at  $E_\alpha = 2.406$  and 3.308 MeV are reported in (1990WE10). The energy of the  $\gamma$ -ray from the decay of  $^{16}\text{O}^*(6.13)$  is  $6129.266 \pm 0.054$  keV (1986AJ04) [based on the  $^{198}\text{Au}$  standard  $E_\gamma = 411804.4 \pm 1.1$  eV]. See also (1982AJ01). Analytical expressions for reaction rates for  $^{13}\text{C}(\alpha, n)^{16}\text{O}$  and other astrophysically important low-mass reactions are given in (1988CA26). See also the related work of (1986SM1A, 1987HA1E, 1989KA24, 1990HO1I).

See Table 16.19. See also (1982AJ01) and  $^{19}\text{F}$  in (1983AJ01).

Table 16.18: Resonances in  $^{13}\text{C} + ^3\text{He}$ <sup>a</sup>

$E(^3\text{He}) (\text{MeV} \pm \text{keV})$	$\Gamma_{\text{c.m.}} (\text{keV})$	Outgoing particles	$^{16}\text{O}^* (\text{MeV})$	$J^\pi; T$
1.55	$\approx 80$	$n_0, n_3$	24.05	
$1.55 \pm 100$	450	$\gamma_0$	24.1

$2.87 \pm 50$	600	$\gamma_0$	25.12	$1^-$
$\approx 3.1$		$\alpha_0, \alpha_2$	$\approx 25.3$	
$\approx 3.5$	$\approx 300$	$\alpha_0$	$\approx 25.6$	$(3^-)$
$\approx 4$	$\approx 300$	$\alpha_0, \alpha_1, \alpha_2$	$\approx 26$	$(3^-)$
$4.0 \pm 100$	b	$\gamma_0, \gamma_{1+2}, \alpha\gamma_{15.1}$	26.0	$1^-; (1)$
$4.6 \pm 100$ <sup>c</sup>	$720 \pm 160$ <sup>c</sup>	$\gamma_2, p_0$	26.5	$2^+, 4^+$
$5.2 \pm 100$	b	$\alpha\gamma_{15.1}$	27.0	( $T = 1$ )
$5.6 \pm 100$	$\approx 600$	$\gamma_0, \gamma_{1+2}, \alpha\gamma_{15.1}, ^8\text{Be}$	27.3	$(1^-)$
$\approx 5.8$	$\approx 2500$	$\gamma_{3+4}$	27.5	
$6.0 \pm 100$	$\approx 500$	$p_0, p_{1+2}, ^3\text{He}, \alpha_1, \alpha_2$	27.7	$(3^-; 0)$
$\approx 6$		$\gamma_0$	28	
$6.5 \pm 100$	b	$\alpha\gamma_{15.1}$	28.1	( $T = 1$ )
$6.8 \pm 100$		$\alpha_0, \alpha_1, \alpha_2$	28.3	( $T = 0$ )
$7.1 \pm 200$		$\gamma_{1+2}$	28.6	
$7.5 \pm 100$	b	$\alpha\gamma_{15.1}$	28.9	( $T = 1$ )
$8.6 \pm 100$	b	$\alpha\gamma_{15.1}$	29.8	( $T = 1$ )
$9.4 \pm 100$	b	$\alpha\gamma_{15.1}$	30.4	( $T = 1$ )
$10.1 \pm 100$	b	$\alpha\gamma_{15.1}$	31.0	( $T = 1$ )

<sup>a</sup> For references see Tables 16.15 in (1971AJ02), 16.13 in (1977AJ02), and 16.15 in (1982AJ01).

<sup>b</sup> Lab widths  $0.5 - 1$  MeV.

<sup>c</sup> Based on  $\Gamma_{\text{c.m.}} = 530 \pm 80$  keV [from  $^{15}\text{N}(p, \gamma)$ , see Table 16.22],  $\Gamma_{p_0} = 150 \pm 45$  keV [ $J^\pi = 2^+$ ],  $110 \pm 35$  keV [ $4^+$ ];  $\Gamma_{p_0}/\Gamma = 0.29 \pm 0.10$  [ $2^+$ ],  $0.21 \pm 0.07$  [ $4^+$ ];  $\Gamma_{\gamma_2} = 740 \pm 240$  eV [ $2^+$ ],  $410 \pm 140$  eV [ $4^+$ ]. See (1977CH16, 1978CH19, 1986AJ04).

See ([1986AJ04](#)).

At  $E(^{13}\text{C}) = 105$  MeV,  $^{16}\text{O}^*(6.05, 6.13, 10.35, 16.3, 20.7)$  are strongly populated: see ([1977AJ02](#), [1982AJ01](#), [1986AJ04](#)). Excitation functions ( $E_{c.m.} = 13.4\text{--}16.8$  MeV) and angular distributions ( $E_{c.m.} = 13.4, 16.38$  MeV) have been measured ([1988JA1B](#)).

See ([1982AJ01](#)).

At  $E(^3\text{He}) = 11$  to  $16$  MeV, neutron groups are observed to  $T = 2$  states at  $E_x = 22.717 \pm 0.008$  and  $24.522 \pm 0.011$  MeV ( $\Gamma < 30$  keV and  $< 50$  keV, respectively). These two states are presumably the first two  $T = 2$  states in  $^{16}\text{O}$ , the analog states to  $^{16}\text{C}^*(0, 1.75)$ .  $J^\pi$  for  $^{16}\text{O}^*(24.52)$  is found to be  $2^+$  from angular distribution measurements ([1970AD01](#)). At  $E(^3\text{He}) = 25.4$  MeV forward angle differential cross sections have been determined to the  $0^+$  states of  $^{16}\text{O}^*(0, 6.05, 12.05)$  ([1986AJ04](#)).

The  $\gamma_0$  yield has been studied for  $E_{\text{d}} = 0.5$  to  $5.5$  MeV. Observed resonances are displayed in Table [16.20](#). Radiative capture in the region of the GDR [ $E_{\text{d}} = 1.5$  to  $4.8$  MeV] has been measured with polarized deuterons. See ([1986AJ04](#)).

For  $E_{\text{d}} = 0.66$  to  $5.62$  MeV, there is a great deal of resonance structure in the excitation curves with the anomalies appearing at different energies at different angles: the more prominent structures in the yield curves are displayed in Table [16.20](#). For polarization measurements see ([1977AJ02](#)) and ([1981LI23](#)) in  $^{15}\text{O}$  ([1986AJ01](#)).

Table 16.19: States of  $^{16}\text{O}$  from  $^{13}\text{C}(^{6}\text{Li}, \text{t})^{16}\text{O}$ 

$E_x$ (MeV $\pm$ keV) <sup>a</sup>	$\Gamma_{\text{c.m.}}$ (keV) <sup>c</sup>	Comments <sup>d</sup>

19.814 $\pm$ 15 <sup>c</sup>	23 $\pm$ 7	
20.5 [u]		very strongly excited

[u] = unresolved.

c.n. = formation appears to be by a compound nuclear process.

m.s. = multistep process.

<sup>a</sup>  $E_x$  without uncertainties are from Table 16.13.

<sup>b</sup> Angular distributions have been reported at  $E(^6\text{Li}) = 25$  MeV to the first seven groups shown here and at 28 MeV: see (1986AJ04) for references. See also (1982AJ01).

<sup>c</sup> Angular distribution at  $E(^6\text{Li}) = 34$  MeV (see 1983KE06, 1986AJ04).

<sup>d</sup> For abbreviations see above. When an  $L$  value is shown, stripping patterns are evident (1983KE06).

<sup>e</sup> There is some evidence for a state at  $E_x = 17.90$  MeV (1983KE06, 1986AJ04).

<sup>f</sup> There is some evidence for a state at  $E_x = 18.46$  MeV with  $\Gamma \approx 60$  keV (1983KE06, 1986AJ04).

Table 16.20: Structure in  $^{14}\text{N} + \text{d}$ <sup>a</sup>

$E_{\text{d}}$ (MeV)	Resonant channel	$\Gamma_{\text{c.m.}}$ (keV)	$J^\pi; T$	$E_x$ (MeV)
1.4	$n_0, \alpha_0$	300 <sup>e</sup>	$0^+ \text{ e}$	22.0
$1.7 \pm 0.1$	$\gamma_0, p_0, p_1, \alpha_0, \alpha_1, \alpha_2, \alpha_3$	400 <sup>e</sup>	$1^- \text{ e}$	22.2
1.85	$n_0, \alpha_0$	175	$2^+ \text{ e}$	22.35
$2.0 \pm 0.1$	$p_0, p_1, \alpha_0, \alpha_3$	350 <sup>e</sup>	$3^- \text{ e}$	22.5
$2.272 \pm 0.005$ <sup>b</sup>	$p_0, p_{1+2}, (p_3), p_4, p_5, \alpha_0, \alpha_2$			22.722
$2.40 \pm 0.05$ <sup>c</sup>	$\gamma_0^{\text{d}}, p_0, p_1$	500 <sup>e</sup>	$1^-; 1$	22.83
2.5	$\alpha_0$			22.9
2.6	$(n_0), \alpha_0, \alpha_1$	200 <sup>e</sup>	$4^+ \text{ e}$	23.0
2.8	$(n_0), p_0, p_1, d_0$	350 <sup>e</sup>	$2^+ \text{ e}$	23.2
3.24	$p_0, p_{1+2}, p_4, p_5, p_6, d_0, \alpha_3$			23.57
4.2	$\gamma_0, (p_0), d_0, \gamma_{15.1}$			24.4
4.58	$(p_0), d_0, \gamma_{15.1}$			24.74
4.9	$n_0, p_0$			25.0
5.95	$d_1, \gamma_{15.1}$			25.9
7.1	$\gamma_{15.1}$			26.9
7.4	$d_2$			27.2
7.7	$d_1$			27.5
(8.5)	$(\gamma_{15.1})$			(28.2)
10.2	$d_2$			29.7

<sup>a</sup> For earlier references see Table 16.14 in (1977AJ02) and 16.16 in (1982AJ01, 1986AJ04).

<sup>b</sup>  $(\Gamma_{d_0} \Gamma_i / \Gamma^2) \times 10^{-3}$  are greater than  $1.6 \pm 0.4$ ,  $0.27 \pm 0.13$ ,  $0.41 \pm 0.15$  and  $0.07 \pm 0.05$  for the  $\alpha_2$ ,  $p_0$ ,  $p_{1+2}$ , and  $p_3$  groups.

<sup>c</sup> If this resonance is fitted with a single-level Breit-Wigner shape, penetrability effects could lower the resonance energy by as much as 50 keV, assuming  $l = 1$ .

<sup>d</sup> The angular distribution of  $\gamma_0$  is consistent with E1.

<sup>e</sup> See references in (1986AJ04).

$$26. \ ^{14}\text{N}(\text{d}, \text{p})^{15}\text{N} \quad Q_{\text{m}} = 8.6087 \quad E_{\text{b}} = 20.7363$$

The yield of various proton groups for  $E_{\text{d}} < 5.0$  MeV shows some fluctuations and two resonances: see Table 16.20 and (1982AJ01). For polarization measurements see (1982AJ01, 1986AJ04). Analyzing power measurements at  $E_{\text{d}} = 70$  MeV are reported in (1986MO27).

$$27. \ ^{14}\text{N}(\text{d}, \text{d})^{14}\text{N} \quad E_{\text{b}} = 20.7363$$

<sup>a</sup> For references see Table 16.17 in (1982AJ01).

<sup>b</sup> Mostly compound nucleus.

<sup>c</sup> Unresolved.

<sup>d</sup> Also reported in  $p\gamma_{4.4}$  coincidences.

<sup>e</sup> Very weak proton group. See (1986AJ04).

<sup>f</sup> (1978FO27) have compared the cross section ratios of these three  $T = 1$  states with their analogs in  $^{16}\text{N}$  populated in the (t, p) reaction: only the  $2^-$  states have the expected cross section ratio of 0.5 for  $(^{3}\text{He}, \text{p})/(t, p)$ . The populations of the  $0^-$  and  $3^-$  states in  $^{16}\text{O}$  are lower by a factor of two.

<sup>g</sup> (1978FO19) suggest that these two states [ $^{16}\text{O}^*(14.93, 15.79)$ ] are  $1^+$  and  $3^+$  2p-2h states with  $T_p = T_h = 0$ .

<sup>h</sup> States at 17.82 and 18.04 ( $\pm 0.04$ ) MeV are also reported in  $p\gamma_{4.4}$  coincidences.

The yield of elastically scattered deuterons has been studied for  $E_d = 0.65$  to 5.5 MeV and for 14.0 to 15.5 MeV: see (1971AJ02, 1977AJ02). There is indication of broad structure at  $E_d = 5.9$  MeV and of sharp structure at  $E_d = 7.7$  MeV in the total cross section of the  $d_1$  group to the  $T = 1$  (isospin-forbidden),  $J^\pi = 0^+$  state at  $E_d = 2.31$  MeV in  $^{14}\text{N}$ . The yield of deuterons ( $d_2$ ) to  $^{14}\text{N}^*(3.95)$  [ $J^\pi = 1^+, T = 0$ ] shows gross structures at  $E_d = 7.4$  and 10.2 MeV (1970DU04):

see Table 16.20 The yield of  $d_1$  has also been studied for  $E_d = 10.0$  to  $17.9$  MeV: see (1982AJ01). For polarization measurements see (1982AJ01, 1986AJ04).

28. (a) $^{14}\text{N}(\text{d}, \text{t})^{13}\text{N}$	$Q_m = -4.2962$	$E_b = 20.7363$
(b) $^{14}\text{N}(\text{d}, {}^3\text{He})^{13}\text{C}$	$Q_m = -2.0571$	

See (1982AJ01).

29. $^{14}\text{N}(\text{d}, \alpha)^{12}\text{C}$	$Q_m = 13.5743$	$E_b = 20.7363$
--	-----------------	-----------------

There is a great deal of structure in the yields of various  $\alpha$ -particle groups for  $E_d = 0.5$  to  $12$  MeV. Broad oscillations ( $\Gamma \sim 0.5$  MeV) are reported in the  $\alpha_0$  and  $\alpha_1$  yields for  $E_d = 2.0$  to  $5.0$  MeV. In addition,  $^{16}\text{O}^*(23.54)$  is reflected in the  $\alpha_3$  yield (see Table 16.20). The yield of  $15.11$  MeV  $\gamma$ -rays, [from the decay of  $^{12}\text{C}^*(15.11)$ ,  $J^\pi = 1^+$ ,  $T = 1$ ] which is isospin-forbidden, has been studied for  $E_d = 2.8$  to  $12$  MeV. Pronounced resonances are observed at  $E_d = 4.2, 4.58$  and  $5.95$  MeV and broader peaks occur at  $E_d = 7.1$  and, possibly, at  $8.5$  MeV: see (1982AJ01). For polarization measurements see (1982AJ01, 1986AJ04).

30. (a) $^{14}\text{N}({}^3\text{He}, \text{p})^{16}\text{O}$	$Q_m = 15.24276$
(b) $^{14}\text{N}({}^3\text{He}, \text{p}\alpha)^{12}\text{C}$	$Q_m = 8.08081$

Observed proton groups are displayed in Table 16.21. Angular distributions have been measured at  $E({}^3\text{He}) = 2.5$  to  $24.7$  MeV: see (1982AJ01). Branching ratios and  $\tau_m$  measurements are shown in Tables 16.13 and 16.14.

31. $^{14}\text{N}(\alpha, \text{d})^{16}\text{O}$	$Q_m = -3.1104$
--	-----------------

Angular distributions to states of  $^{16}\text{O}$  have been reported at many energies to  $E_\alpha = 48$  MeV: see (1971AJ02, 1977AJ02). Among the states which have been reported [see Table 16.7 in (1977AJ02)] are  $^{16}\text{O}^*(11.094 \pm 3, 13.98 \pm 50, 14.32 \pm 20, 14.400 \pm 3, 14.815 \pm 2, 15.17 \pm 50, 15.44 \pm 50, 15.78 \pm 50, 16.214 \pm 15, 17.18 \pm 50)$  [MeV  $\pm$  keV]: the results are consistent with  $J^\pi = 5^+, 6^+, 4^+$  for  $^{16}\text{O}^*(14.40, 14.82, 16.29)$  [2p-2h] and with  $6^+$  for  $^{16}\text{O}^*(16.30)$  [4p-4h]. [See refs. in (1977AJ02).] Work reported in (1979CL10) and reviewed in (1982AJ01) determined  $\Gamma_{\text{c.m.}} = 34 \pm 12, 27 \pm 5$  and  $70 \pm 8$  keV, respectively for  $^{16}\text{O}^*(14.31 \pm 10, 14.40 \pm 10, 14.81)$ .

Table 16.22: Levels of  $^{16}\text{O}$  from  $^{15}\text{N}(\text{p}, \gamma)$ ,  $^{15}\text{N}(\text{p}, \text{p})$  and  $^{15}\text{N}(\text{p}, \alpha)$

33. (a) $^{14}\text{N}(^{11}\text{B}, ^9\text{Be})^{16}\text{O}$	$Q_m = 4.9208$
(b) $^{14}\text{N}(^{12}\text{C}, ^{10}\text{B})^{16}\text{O}$	$Q_m = -4.4503$
(c) $^{14}\text{N}(^{13}\text{C}, ^{11}\text{B})^{16}\text{O}$	$Q_m = 2.0575$
(d) $^{14}\text{N}(^{14}\text{N}, ^{12}\text{C})^{16}\text{O}$	$Q_m = 10.46390$

For reactions (a) and (c) see ([1982AJ01](#)). For reactions (b), (c), and (d) see ([1986AJ04](#)).

The yield of  $\gamma$ -rays has been measured for  $E_p = 0.15$  to  $27.4$  MeV [see ([1986AJ04](#))] and for  $E_p = 6.25$ – $13.75$  MeV ([1988WI16](#)),  $20$ – $100$  MeV ([1988HA04](#)),  $20$ – $90$  MeV ([1989KA02](#)), and  $10$ – $17$  MeV ([1987BA71](#)): observed resonances are displayed in Table [16.22](#). The  $\gamma_0$  cross section shows a great deal of structure up to  $E_p = 17$  MeV. Above that energy the  $\gamma_0$  yield decreases monotonically. Besides the GDR which peaks at  $^{16}\text{O}^*(22.15)$  there is evidence for the emergence of a giant structure (E2) with  $E_x = 24$ – $29$  MeV in the  $\gamma_{1+2+3+4}$  yield ([1978OC01](#)). Measurements for ( $\text{p}, \gamma_0$ ) cross sections and analyzing powers for  $E_p = 6.25$ – $13.75$  MeV indicated a clear enhancement of the E2 cross section above  $E_x = 22$  MeV. Differential cross sections for  $\gamma_0$  and several other (unresolved)  $\gamma$ -rays at  $E_p \approx 28$  to  $48$  MeV generally show a broad bump at  $E_x \approx 34 \pm 2$  MeV. The angular distributions show a dominant E1 character ([1986AJ04](#)). See also ([1988HA04](#), [1988KI1C](#), [1989BOYV](#)) and the review of ([1988HA12](#)). For comparisons with measurements of the inverse reaction see ([1991FI08](#)).

Measurements of ( $\text{p}, \gamma_1$ ) yields ([1987BA71](#)) indicated a pronounced concentration of dipole strength which was interpreted as an E1 giant resonance built on the  $^{16}\text{O}$  first excited state. Other measurements of proton capture to excited states for  $E_p = 20$ – $90$  MeV are reported in ([1989KA02](#)).

Cross sections and analyzing powers for capture into the  $3^-$  state at  $E_x = 6.13$  MeV were studied by ([1988RA15](#)). Studies of quadrupole and octupole radiation from  $^{16}\text{O}$  at  $E_x = 39$  MeV determine  $\sigma_{\text{E}2}/\sigma_{\text{E}1} = 0.124 \pm 0.015$ , and  $\sigma_{\text{E}3}/\sigma_{\text{E}1} = 0.0051 \pm 0.0026$  ([1989KO29](#)).

A study of the M1 decays of  $^{16}\text{O}^*(16.21, 17.14)$  [both  $J^\pi; T = 1^+$ ; 1] to  $^{16}\text{O}^*(6.05)$  finds  $B(\text{M}1, 1^+ \rightarrow 0_2^+)/B(\text{M}1, 1^+ \rightarrow 0_1^+) = 0.48 \pm 0.03$  and  $0.55 \pm 0.04$ , respectively.  $^{16}\text{O}^*(18.03)$  is a  $3^-$ ; 1 state with a strength  $\Gamma_p \Gamma_{\gamma_2} / \Gamma = 1.96 \pm 0.27$  eV and  $^{16}\text{O}^*(18.98)$  is the  $4^-$ ; 1 stretched particle-hole state with a strength of  $(0.85 \pm 0.10)$  eV ([1983SN03](#)). See also ([1983SN03](#)) for the identification of analog states in  $^{16}\text{N}$  and in  $^{16}\text{O}$ , and for a discussion of Gamow-Teller matrix elements in  $A = 14$ – $18$  nuclei. See also the review of ([1987BE1G](#)). A study of the strong M2 transitions  $E_x = 12.53 \rightarrow 0$  MeV and  $E_x = 12.97 \rightarrow 0$  MeV is reported in ([1986ZI08](#)).

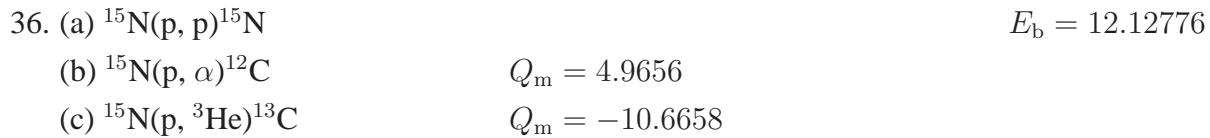

For astrophysical considerations see (1986AJ04) and (1985CA41, 1988CA26, 1989BA2P). See also Table 16.14 here. An application of this reaction for thin film analysis is described in (1992EN02).

Calculations of the decay of the GDR and GQR by (1990BU27) have included 1p-1h and 2p-2h configurations, but the fine structure of the GDR remains unexplained. RPA calculations overestimate  $p_0$  decay but the use of a non-local mean field partially corrects this. The ISGQR is misplaced by RPA calculations, but is lowered by coupling to  $\alpha$ - $^{12}\text{C}$  channels. Data from ( $e, e'\alpha$ ) experiments are needed. RPA spectra have been examined (1988BL10) using a relativistic Hartree-Fock model for the ground state. Hartree-Fock based calculations appear to be insensitive to short-range repulsion.  $1^-$  and  $T = 1$  strength distributions for  $^{16}\text{O}$  have been calculated using Hartree and Hartree-Fock methods. Shell-model plus  $R$ -matrix and continuum shell-model results for 1p shell nuclei have been considered (1987KI1C), but underestimate ground state ( $\gamma, N_0$ ) decay branches. Ground state shell-model plus  $R$ -matrix calculations describe the GDR region reasonably well.

Excitation functions and cross sections have been measured for  $E_p = 3.8$  to  $19.0$  MeV: see (1982AJ01). For a listing of observed resonances see Table 16.23. (1983BY03) have measured the polarization and analyzing power for the  $n_0$  group for  $E_p = 4.5$  to  $11.3$  MeV and have deduced integrated cross sections. Differential cross sections and analyzing powers at  $E_p = 200$  and  $494$  MeV have been measured (1988CIZZ). See also (1986AJ04).

The theoretical work of (1987BE1D) has shown the sensitivity of the ( $p, n$ ) reaction to spin dynamics and pionic fields for  $E_p = 150$ – $500$  MeV and isovector density below  $50$  MeV. The importance of configuration mixing in Gamow-Teller quenching is also considered. The authors of (1989RA15) discuss the failure of the DWIA to explain the analyzing power for ( $p, n$ ) at  $500$  MeV, focusing on transverse and longitudinal spin-flip cross sections and projectile no-spin-flip cross sections as the sensitive terms primarily responsible for the inadequacies of this method.

Elastic scattering studies have been reported for  $E_p = 0.6$  to  $15$  MeV and angular distributions and excitation functions have been measured for  $E_p = 2.5$  to  $9.5$  MeV for the ( $p_{1+2}\gamma$ ) and ( $p_3\gamma$ ) transitions [see (1986AJ04)]. Measurements of the depolarization parameter  $K_y^{y'}$  at  $E_p = 65$  MeV are reported in (1990NA15). Excitation functions for  $\alpha_0$  and  $\alpha_1$  particles [corresponding to  $^{12}\text{C}^*(0, 4.43)$ ] and of  $4.43$  MeV  $\gamma$ -rays have been measured for  $E_p = 93$  keV to  $45$  MeV [see (1982AJ01)] and at  $E_p = 77.6$  keV to  $9.5$  MeV (1986AJ04). The yield of  $15.1$  MeV  $\gamma$ -rays has been measured for  $E_p = 12.5$  to  $17.7$  MeV (1978OC01). Measurements of the  $430$  keV

<sup>a</sup> For references see Table 16.19 in (1982AJ01).

<sup>b</sup> Assignments are from (p, n) and (p,  $\gamma$ ) results. The  $T$ -assignments are made on the basis of energy and width comparisons with states of  $^{16}\text{N}$ .

<sup>c</sup> Probably a doublet.

<sup>d</sup> Values of  $(2J + 1)\Gamma_{\text{p}_0}\Gamma_{\text{n}_0}/\Gamma^2$  are derived for this resonance and the ones below: see (1978CH09).

resonance in  $^{15}\text{N}(\text{p}, \alpha\gamma)^{12}\text{C}$  were carried out by (1987OS01, 1987EV01). Observed anomalies and resonances are displayed in Table 16.22. The resonance at  $E(^{15}\text{N}) = 6.4$  MeV observed in the reaction  $^1\text{H}(^{15}\text{N}, \alpha\gamma)^{12}\text{C}$  has been used extensively to determine hydrogen concentration in thin films. See (1987EV01, 1987OS01, 1990FU06, 1990HJ02, 1992FA04).

A phase shift analysis of angular distributions of cross section and analyzing power for elastic scattering has yielded information on many  $^{16}\text{O}$  states in the range  $E_x = 14.8$  to  $18.6$  MeV. In particular a broad  $J^\pi = 2^-$ ,  $T = 1$  state at  $17.8$  MeV appears to be the analog of the  $1\text{p}-1\text{h}$  ( $d_{3/2}$ ,  $p_{1/2}^{-1}$ )  $^{16}\text{N}$  state at  $E_x \approx 5.0$  MeV (1986AJ04). The isospin mixing of the  $2^-$  states  $^{16}\text{O}^*(12.53, 12.97)$  has been studied by (1983LE25): the charge-dependent matrix element responsible for the mixing is deduced to be  $181 \pm 10$  keV. The  $\alpha_0$  yield and angular distribution study by (1982RE06) leads to a zero-energy intercept of the astrophysical  $S(E)$  factor,  $S(0) = 65 \pm 4$  MeV·b. See (1982AJ01, 1986AJ04) for the earlier work. See also (1987RO25), and see the tables of thermonuclear reaction rates in (1985CA41).

Among recent theoretical developments related to these reactions, electron screening effects for  $^{15}\text{N}(\text{p}, \alpha)^{12}\text{C}$  at very low energies ( $< 50$  keV) have been evaluated (1987AS05). Expressions for longitudinal and irregular transverse PNC analyzing powers in cases of parity-mixed resonances such as  $^{15}\text{N}(\vec{p}, \text{p})^{15}\text{N}$  and  $^{15}\text{N}(\vec{p}, \alpha)^{12}\text{C}$  are derived in (1989CA1L). Recent theoretical studies of the parity- and isospin-forbidden  $\alpha$ -decay of the  $12.97$  MeV state to the  $^{12}\text{C}$  ground state are reported in (1991DU04, 1991KN03). See also the theoretical study of single particle resonances in (1991TE03).

An investigation into the separation of the strength of the giant resonance for underlying levels neglecting statistical assumptions (1986KL06) has shown deviations from statistical behavior at the tops of resonances, leading to missing spectroscopic strength. A calibration method for heavy-ion accelerators has been described by (1987EV01), who have also determined the energy of the  $E_p = 430$  keV resonance in the  $^{15}\text{N}(\text{p}, \alpha\gamma)^{12}\text{C}$  reaction. Quantum fluctuations are shown to cause structures having collective properties (1986RO26). These new collective states are dissipative.  $^{15}\text{N}(\text{p}, \text{p})^{15}\text{N}$  is considered for  $25 < E_p < 40$  MeV. (1988RO09) consider the transition from resonance to direct reactions as well as the significance of quantum fluctuations.

Observed neutron groups,  $l$ -values and spectroscopic factors are displayed in Table 16.24. See also (1986AJ04).

See Table 16.24.

Table 16.24: States in  $^{16}\text{O}$  from  $^{15}\text{N}(\text{d}, \text{n})$  and  $^{15}\text{N}(^3\text{He}, \text{d})$

<sup>f</sup> See also (1993CH06).

The ground state of  $^{16}\text{N}$  decays to seven states of  $^{16}\text{O}$ : reported branching ratios are listed in Table 16.25. The ground state transition has the unique first-forbidden shape corresponding to  $\Delta J = 2$ , fixing  $J^\pi$  of  $^{16}\text{N}$  as  $2^-$ : see (1959AJ76). The unique first-forbidden decay rates to the  $0^+$  ground state and 6.06-MeV level are well reproduced by a large-basis  $(0 + 2 + 4)\hbar\omega$  shell-model calculation (1992WA25). The decays to odd-parity states (see Table 16.25) are well reproduced by recent calculations of Gamow-Teller matrix elements (1993CH06). For the  $\beta$ -decay of  $^{16}\text{N}^*(0.12)$ , see Reaction 1 in  $^{16}\text{N}$ .

The  $\beta$ -delayed  $\alpha$ -decays of  $^{16}\text{O}^*(8.87, 9.59, 9.84)$  have been observed: see (1971AJ02). The parity-forbidden  $\alpha$ -decay from the  $2^-$  state  $^{16}\text{O}^*(8.87)$  has been reported:  $\Gamma_\alpha = (1.03 \pm 0.28) \times 10^{-10}$  eV [ $E_\alpha = 1282 \pm 5$  keV]: see (1977AJ02).

Transition energies derived from  $\gamma$ -ray measurements are:  $E_x = 6130.40 \pm 0.04$  keV [ $E_\gamma = 6129.142 \pm 0.032$  keV (1982SH23)],  $E_x = 6130.379 \pm 0.04$  [ $E_\gamma = 6129.119 \pm 0.04$  keV (1986KE15)] and  $E_x = 7116.85 \pm 0.14$  keV [ $E_\gamma = 7115.15 \pm 0.14$  keV]. See (1977AJ02). See also p. 16 in (1982OL01).

See (1990JI02) for an R-matrix analysis for the 9.59-MeV level and discussion of its astrophysical significance and see astrophysical related work of (1991BA1K, 1991HU10).

$$40. (\text{a}) \ ^{16}\text{O}(\gamma, \text{n}) ^{15}\text{O} \quad Q_m = -15.6639$$

(b) $^{16}\text{O}(\gamma, 2\text{n})^{14}\text{O}$	$Q_m = -8.8863$
(c) $^{16}\text{O}(\gamma, \text{pn})^{14}\text{N}$	$Q_m = -22.9609$
(d) $^{16}\text{O}(\gamma, 2\text{p})^{14}\text{C}$	$Q_m = -22.178$
(e) $^{16}\text{O}(\gamma, 2\text{d})^{12}\text{C}$	$Q_m = -31.0087$

The absorption cross section and the ( $\gamma$ , n) cross section are marked by a number of resonances. On the basis of monoenergetic photon data, excited states of  $^{16}\text{O}$  are observed at  $E_x = 17.3$  [u], 19.3 [u] and 21.0 MeV [u=unresolved], followed by the giant resonance with its principal structures at 22.1 and 24.1 MeV, and with additional structures at 23 and 25 MeV: see (1986AJ04, 1988DI02). The integrated nuclear absorption cross section for  $E_\gamma = 10$  to 30 MeV is  $182 \pm 16$  MeV·mb (1986AJ04). See also Reaction 42. The ( $\gamma$ , n) cross section has been measured for  $E_\gamma = 17$  to 33 MeV: in that energy interval the ( $\gamma$ , 2n) cross section is negligible. The cross section for formation of the GDR at 22.1 MeV is  $10.0 \pm 0.4$  mb and the integrated cross section to 30 MeV is  $54.8 \pm 5$  MeV·mb. There is apparently significant single particle-hole excitation of  $^{16}\text{O}$  near 28 MeV and significant collectivity of the GDR. A sharp rise is observed in the average  $E_n$  above 26 MeV. The cross section for ( $\gamma$ ,  $n_0$ ) decreases monotonically for  $E_x = 25.5$  to 43.8 MeV. In the range 30–35 MeV the E2 cross section exhausts about 4% of the isovector E2 EWSR. Over the range 25.5 to 43.8 MeV it exhausts  $\sim 68\%$  of the isovector E2 EWSR [see (1986AJ04) and references cited there]. M1, E1, and E2 strengths were studied by recent polarization and cross section measurements for  $E_\gamma = 17$  to 25 MeV (1991FI08). An atlas of photoneutron cross sections obtained with monoenergetic photons is presented in (1988DI02).

The absorption cross section has been measured with bremsstrahlung photons of energies from  $E_{bs} = 10$  MeV to above the meson threshold: see (1982AJ01). The ( $\gamma$ , n), ( $\gamma$ , 2n) and ( $\gamma$ , Tn) cross sections have been studied with monoenergetic photons for  $E_\gamma = 24$  to 133 MeV. Above 60 MeV, the main reaction mechanisms appear to be absorption of the photons by a correlated n-p pair in the nucleus: the integrated cross section from threshold to 140 MeV is  $161 \pm 16$  MeV·mb (1986AJ04). Differential cross sections for ( $\gamma$ ,  $n_0$ ) have been measured at  $E_\gamma = 150$ , 200, and 250 MeV at  $\theta_{lab} = 49^\circ$ ,  $59^\circ$ , and  $88^\circ$  (1988BE20, 1989BE14). See also  $^{15}\text{O}$  in (1991AJ01). For reaction (b) and pion production see (1986AJ04). For reaction (c) measurements have been carried out with bremsstrahlung photons with  $E_\gamma \leq 150$  MeV (1989VO19), and with tagged photons in the  $\Delta(1232)$  resonance region (1987KA13). See also (1991VA1F). Measurements of reactions (d) and (e) were made with tagged photons of energies 80–131 MeV (1991MA39). Measurements of the total cross section at  $E_\gamma = 90$ –400 MeV are described in (1988AH04). Calculations which indicate that molecular effects are important in screening corrections to the cross section in the  $\Delta$  resonance region are discussed. The hadron production cross section has been studied over the range 0.25 to 2.7 GeV see (1986AJ04).

Sum rules and transition densities for isoscalar dipole resonances are discussed in (1990AM06). For a calculation of monopole giant resonances see (1990AS06). Calculations relating to polarization effects are discussed in (1990BO31, 1990LO20). The contribution of six-quark configurations to the E1 sum rule has been considered (1989AR02), and upper bounds for the production probabilities of 6q-clusters have been derived. The continuum self-consistent RPA-SK3 theory predicts

charge transition densities in  $^{16}\text{O}$  for excitation of GDR ([1988CA07](#)). Neutron and proton decay is also indicated. See also ([1991LI28](#), [1991LI29](#)). A continuum shell model description of  $(\gamma, n)$  and  $(\gamma, p)$  data at medium energies is reported in ([1990BRZY](#)). Radial dependence of charge densities depends on whether r-values correspond to the interior of the nucleus or to the surface ([1988CA07](#)). In ([1985GO1A](#))  $(\gamma, n)$  and  $(\gamma, p)$  experimental results are compared with those of large-basis shell model calculations. Good results were obtained, but a new source of spreading is warranted. Ratios of  $(\gamma, n)$ -to- $(\gamma, p)$  cross sections have been computed using R-matrix theory including configuration splitting, isospin splitting, and kinematics effects ([1986IS09](#)). Computations of the partial photonuclear cross sections have been performed ([1987KI1C](#)) using the continuum shell model. GDR and other giant multipole resonances are also considered. The authors of ([1988RO1R](#)) use the continuum shell model as a basis for their study of “self-organization”. The role of the velocity-dependent part of the N-N interaction is also examined. A method for solving the RPA equations, and an examination of the long-wavelength approximation is discussed in ([1988RY03](#)). Levinger’s modified quasi-deuteron model is applied for  $7 \leq A \leq 238$  and  $E_\gamma = 35\text{--}140$  MeV ([1989TE06](#)). The quantities  $L = 6.1 \pm 2.2$  and  $D = 0.72$   $A$  are also deduced. The role of distortion in  $(\gamma, np)$  reactions is explored in ([1991BO29](#)).

41. (a) $^{16}\text{O}(\gamma, p)^{15}\text{N}$	$Q_m = -12.12776$
(b) $^{16}\text{O}(\gamma, d)^{14}\text{N}$	$Q_m = -20.7363$
(c) $^{16}\text{O}(\gamma, \alpha)^{12}\text{C}$	$Q_m = -7.16195$
(d) $^{16}\text{O}(\gamma, \pi^0)^{16}\text{O}$	$Q_m = -134.964$
(e) $^{16}\text{O}(\gamma, \pi^+)^{16}\text{N}$	$Q_m = -149.986$
(f) $^{16}\text{O}(\gamma, \pi^-)^{16}\text{F}$	$Q_m = -154.984$
(g) $^{16}\text{O}(\gamma, \pi^- p)^{15}\text{O}$	$Q_m = -154.4485$

The  $(\gamma, p_0)$  cross section derived from the inverse capture reaction (reaction 34) confirms the giant resonance structure indicated above in Reaction 40, as do the direct  $(\gamma, p_0)$  measurements. For the earlier work see ([1982AJ01](#)). For results of measurements with linear polarized photons at  $E_{bs} = 22$  and 30 MeV and for differential cross sections at  $E_\gamma = 101.5\text{--}382$  MeV and proton spectra at  $E_\gamma \approx 360$  MeV, see ([1986AJ04](#)). See also the reviews ([1987BE1G](#), [1988KO1S](#)), and see ([1987MA1K](#)). Angular distributions for  $(\gamma, p)$  reactions populating low-lying states of  $^{15}\text{N}$  were measured ([1988AD07](#)) with bremsstrahlung photons with  $E_\gamma = 196\text{--}361$  MeV. Differential cross sections measurements with  $E_\gamma \approx 300$  MeV tagged photons ([1990VA07](#)) were used to study the interaction mechanism. Proton spectra measured at  $90^\circ$  ([1990VA07](#)) showed evidence for an absorption process in which the photon interacts with a  $T = 1$  np pair. See also the comment ([1992SI01](#)) and reply on the interpretation of these data. A related calculation concerning quasideuteron behavior of np pairs is described in ([1992RY02](#)). See also ([1987OL1A](#)).

For reaction (b) see ([1982AJ01](#)). A study of the  $^{16}\text{O}(\gamma, \alpha_0)$  reaction (c) at  $\theta = 45^\circ$  and  $90^\circ$  shows a  $2^+$  resonance at  $E_x = 18.2$  MeV with an E2 strength which is spread out over

a wide energy interval. A strong resonance corresponding to an isospin-forbidden  $1^-$  state at  $E_x \approx 21.1$  MeV is also observed ([1986AJ04](#)). The systematics of cross sections for reaction (d) are discussed in ([1991BO26](#)). For pion production reactions (e), pion angular distributions were measured for a mixed flux of real and virtual photons at  $E_\gamma = 320$  MeV ([1987YA02](#)). Double differential cross sections with tagged photons with  $E_\gamma = 220\text{--}450$  MeV are reported in ([1991AR06](#)). See also  $^{16}\text{N}$  and ([1986AJ04](#)). Exclusive cross sections for reaction (g) in the  $\Delta$  resonance region are reported by ([1992PH01](#)).

Recent theoretical work includes calculations of sum rules and transition densities ([1990AM06](#)), monopole giant resonances ([1990AS06](#)), and polarization effects ([1990BO31](#), [1990LO20](#)). A scheme using fractional-parentage coefficients to separate the wavefunction into three fragments in arbitrary internal states has been proposed, and examples include  $^7\text{Li}(\gamma, t)^4\text{He}$ ,  $^{16}\text{O}(\gamma, dd)^{12}\text{C}$  and  $^{12}\text{C}(\gamma, pd)^9\text{Be}$  ([1988BU06](#)). A formula for cross sections for  $A(\gamma, d\gamma')A - 2$  reactions with  $E_\gamma = 2.23$  MeV has been derived ([1988DU04](#)). In a study of Dirac negative energy bound states, a relativistic shell model predicts  $\gamma + ^{16}\text{O} \rightarrow {}_{\bar{p}}^{15}\text{N} + p$  has a threshold at 1.2 GeV and rises to about 5  $\mu\text{b}$  by 1.6 GeV ([1988YA08](#)). ([1988LO07](#)) calculate  $^{16}\text{O}(\gamma, p){}^{15}\text{N}$  using Dirac phenomenology. Dirac spinors are used to describe the proton dynamics in a DWBA calculation, and results are compared to data.  $^{16}\text{O}(\gamma, p){}^{15}\text{N}$  for  $E_\gamma = 50\text{--}400$  MeV has been calculated ([1986LU1A](#)) using a coupled-channels continuum shell-model technique. A single particle direct knock-out model is used by ([1987RY03](#)) to calculate  $(\gamma, \pi)$  cross sections for  $E_\gamma = 40\text{--}400$  MeV. See also ([1990BRZY](#), [1991IS1D](#)).  $^{16}\text{O}(\gamma, p)$  at intermediate energies has been calculated using both a single particle and a pion-exchange-current mechanism in a relativistic form of the nucleon current operator and four-component nucleon wave functions ([1988MC03](#)). See also the study of the effects of current conservation in these reactions ([1991MA39](#)) and of scaling ([1991OW01](#)). An expression for the  $(\gamma, N)$  cross section with incident circularly polarized photons and outgoing nucleon polarization being detected is given in ([1986PO14](#)). A direct-semidirect model calculation for  $^{16}\text{O}(\gamma, N_0)$  at 60 MeV is given as an example. A model, based on basic interactions between photons, pions, nucleons and isobars, providing an adequate description of the  $\gamma N \rightarrow \pi N$  reaction is described in ([1992CA04](#)).

#### 42. $^{16}\text{O}(\gamma, \gamma){}^{16}\text{O}$

Resonances have been reported ([1970AH02](#)) at  $E_\gamma = 22.5 \pm 0.3$ ,  $25.2 \pm 0.3$ ,  $31.8 \pm 0.6$  and  $50 \pm 3$  MeV: the dipole sum up to 80 MeV exceeds the classical value by a factor 1.4. Elastic photon scattering cross sections for  $E_\gamma = 25$  to 39 MeV have been measured. The E2 strength is  $1.25_{-0.9}^{+1.3}$  times the total EWSR strength over that interval. The widths of  $^{16}\text{O}^*(6.92, 7.12)$  are, respectively,  $94 \pm 4$  and  $54 \pm 4$  meV ([1985MO10](#), [1986AJ04](#)). Differential cross sections at angles of  $135^\circ$  and  $45^\circ$  for elastic scattering of tagged photons between 21.7 and 27.5 MeV in the giant dipole resonance region have been measured by ([1987LE12](#)). Differential cross sections for tagged photons with  $E_\gamma = 27\text{--}68$  MeV have been reported by ([1990MEZV](#)). Polarizabilities of nucleons imbedded in  $^{16}\text{O}$  were measured via Compton scattering of 61 and 77 MeV photons by ([1992LU01](#)). See also Table 16.14.

A non-perturbative study of damping of dipole and quadrupole motion in  $^{16}\text{O}$  is discussed in (1992DE06). (1987VE03) have used an extended isobar doorway model including open-shell configurations in both ground and excited states to calculate elastic and inelastic photon scattering in the  $\Delta$ -region, and for linearly polarized photons.

Table 16.26: Excited states observed in  $^{16}\text{O}(\text{e}, \text{e}')^{16}\text{O}$  <sup>a</sup>

$E_x$ (MeV $\pm$ keV)	$J^\pi; T$	Mult.	$\Gamma_{\text{c.m.}}$ (keV)	$\Gamma_{\gamma_0}$ (eV)

<sup>a</sup> See also Table 16.26 in (1971AJ02). For references see Table 16.24 in (1977AJ02). See also the text.

<sup>b</sup> (1985HY1A: momentum transfer range 0.8 to 2.5 fm<sup>-1</sup>). See (1986AJ04).

<sup>c</sup> Monopole matrix element in fm<sup>2</sup>.

<sup>d</sup> (1983KU14).

<sup>e</sup> An unresolved complex of M1 strength has a centroid at  $E_x \approx 17.7$  MeV: the total  $\Gamma_{\gamma_0}$  is  $7.4 \pm 1.9$  eV (1983KU14).

<sup>f</sup> (1987HY01).

<sup>g</sup> See also (1986AJ04).

<sup>h</sup> The total cross section ( $E_x = 18.7 - 19.4$  MeV) is 12% M1 and 88% M2, leading to  $B(\text{M1}) \uparrow = 0.13 \pm 0.03 \mu_N^2$  and  $B(\text{M2}) \uparrow = 341 \pm 51 \mu_N^2 \cdot \text{fm}^2$ : see (1986AJ04).

43. (a)  $^{16}\text{O}(\text{e}, \text{e})^{16}\text{O}$

$$(\text{b}) \quad ^{16}\text{O}(\text{e}, \text{e}'\text{p})^{15}\text{N} \quad Q_m = -12.12776$$

$$(\text{c}) \quad ^{16}\text{O}(\text{e}, \text{e}'\alpha)^{12}\text{C} \quad Q_m = -7.161$$

The  $^{16}\text{O}$  charge radius =  $2.710 \pm 0.015$  fm (1978KI01). Form factors for transitions to the ground and to excited states of  $^{16}\text{O}$  have been reported in many earlier studies [see (1982AJ01, 1986AJ04)], and by (1987HY01); see Table 16.26. Table 16.26 lists the excited states observed from  $(\text{e}, \text{e}')$ . The form factor for  $^{16}\text{O}^*(9.84)$  indicates a transition density peaked in the interior (1986BU02). The energy-weighted M2 strength is nearly exhausted by the M2 states which have been observed. The isospin-forbidden (E1) excitation of  $^{16}\text{O}^*(7.12)$  is reported: the isovector contribution interferes destructively with the isoscalar part and has a strength  $\sim 1\%$  of the  $T = 0$  amplitude. The  $0^+$  states of  $^{16}\text{O}^*(6.05, 12.05, 14.00)$  saturate  $\sim 19\%$  of an isoscalar monopole sum rule. In a recent measurement, the magnetic monopole  $0^+ \rightarrow 0^-$  transition to  $^{16}\text{O}^*(10.957)$  was observed (1991VO02). The E2 strength is distributed over a wide energy region: see Table 16.26, and (1982AJ01, 1986AJ04) for references. See also the compilation of nuclear charge density distribution parameters (1987DEZV), and the reviews of (1989DR1C, 1987HO1F).

A study of reaction (b) at 500 MeV shows separation energies of 12.2 and 18.5 MeV, corresponding to  $^{15}\text{N}^*(0, 6.32)$ . The momentum distribution of the recoiling nucleus has been measured. High precision data with  $\sim 100$  keV resolution in the missing mass are reviewed in (1990DE16). The excitation of  $^{16}\text{O}^*(11.52, 12.05, 22.3)$  and some other states is reported at  $E_e = 112 - 130$  MeV in  $(\text{e}, \text{e}')$ . The  $(\text{e}, \text{e}'\text{p})$  and  $(\text{e}, \text{e}\alpha)$  processes lead to the excitation of  $^{15}\text{N}^*(0, 6.32)$  and of  $^{12}\text{C}^*(0, 4.44)$ . (See (1982AJ01, 1986AJ04) for the references). In a recent measurement the nuclear response function  $R_{LT}$  for  $^{15}\text{N}^*(0, 6.32)$  was determined in  $(\text{e}, \text{e}'\text{p})$  by (1991CH39). See also (1990MO1K). Coincidence experiments at  $E_e = 130$  MeV are reported by (1987DM01). See also (1987RI1A). Non-spherical components in the  $^{16}\text{O}$  ground state are indicated by the  $(\text{e}, \text{e}'\text{p})$  data of (1988LEZW). The inelastic cross section for 537 and 730 MeV electrons has been measured by (1987OC01), and the electromagnetic excitation of the  $\Delta$  resonance was studied.

Angular correlation measurements for reaction (c) to determine isoscalar E2 strengths in  $^{16}\text{O}$  are reported in (1992FR05).

Inelastic electron-nucleus interactions for  $^{16}\text{O}$  at 5 GeV are reported in (1990DE1M).

In theoretical work on reactions (a) and (b), models for relativistic Coulomb sum rules are developed in (1989DO05). See also (1991LE14). A shell-model study of giant resonances and spectroscopic factors in  $^{16}\text{O}$  is described in (1988HO10). See also (1990BO31). (1988AM03) studied an isoscalar dipole excitation in  $^{16}\text{O}$  (7.12 MeV state). Core polarization was used in their limited shell model treatment. Exchange amplitudes proved crucial in fitting  $(\text{p}, \text{p}')$  data. A relativistic Dirac-Hartree-Fock approach is shown to give a reasonably good account of binding energies, single-particle energies and charge, as well as proton and neutron densities of  $^{16}\text{O}$  and other closed shell nuclei (1988BL11). The application of Monte Carlo methods in light nuclei including  $^{16}\text{O}$  is reviewed in (1991CA35). Non-locality of the nucleon-nucleus optical potential has been used (1987BO54) to evaluate the missing single particle strength observed in  $(\text{e}, \text{e}'\text{p})$  data. (1988BO40) have studied the charge form factor by taking the one- and two-body isoscalar charge operands into account in the topological soliton model. Nuclear responses were calculated (1987CA16) using self-consistent HF and RPA theory with a SK3 interaction. Decay properties in  $(\text{e}, \text{e}'\text{p})$  and  $(\text{e}, \text{e}'\text{n})$  for semidirect and knockout processes are also discussed. A self-consistent RPA with the SK3 interaction has been used by (1988CA10) to calculate  $(\vec{\text{e}}, \text{e}'\text{x})$  reactions. Polarization structure functions are also discussed. (1989CA13) use self-consistent RPA with SK3 interactions to calculate monopole excitations in  $(\text{e}, \text{e}')$  and  $(\vec{\text{e}}, \text{e}'\text{x})$  reactions. Evidence has been presented by (1989FR02) for a violation of Siegert's theorem, based on cross section measurements of the electro-excitation of the first  $1^-$  level in  $^{16}\text{O}$ . Previous Hartree-Fock calculations were used by (1990CA34) to study Siegert's Theorem in E1 decay in  $^{16}\text{O}$ . Their results show that the previously claimed violation cannot be definitely asserted. A pole graph method is used by (1987CH10) to calculate production of hypernuclei in the continuum. Radial wave functions obtained from realistic nuclear potentials have been used to calculate electron scattering form factors for stretched configurations, which are compared to data (1988CL03). (1987CO24) exhibit and discuss DWBA structure functions for  $(\vec{\text{e}}, \text{e}'\text{x})$  cross sections. A numerical study of the decay of giant resonances of  $^{16}\text{O}$  was also conducted. The ratio of transverse-to-longitudinal electromagnetic response in  $(\text{e}, \text{e}'\text{p})$  reactions has been examined in terms of relativistic dynamics and medium modifications (1987CO26). Electron scattering form factors have been calculated (1990DA14) using relativistic self-consistent RPA descriptions of discrete excitations. (1986GU05) derived an expression for the transition charge density in the Helm model, and (1988GU03) calculated charge density distributions using harmonic oscillator wave functions. Experimental values have been compared with calculated transition charge densities from various models in (1988GU14). (1988KU18) calculated binding energy, excitation spectra to  $\sim 12$  MeV, and e-scattering form factors using the mean-field approximation and the BZM boson image of the shell model Hamiltonian. Results appear superior to the standard shell model. The two-body pion exchange current contributions to the form factor of inelastic electron scattering has been calculated by (1986LA15) using the effective pion propagator approximation. Effects due to meson exchange currents and unbound wavefunctions for the valence nucleon were included in calculations of electron scattering form factors (1987LI30). Special attention was paid to  $1\hbar\omega$  stretched states. A Sum Rule formalism was used by (1989LI1G) to investigate giant resonances. Surface effects, non-Hermitian operators, and magnetic excitations were considered.

Normalized correlated wavefunctions were used by (1988MA29) to simplify a previously derived expression for the charge form factor in the non-unitary model operator approach, and compared to data. (1989MA06, 1990MA63) derived an approximate formula for the two-body term in the cluster expansion of the charge form factor, and discussed the correlation parameter. (1989MC05) used the Gelerkin approach to calculate a finite nucleus Dirac mean field spectrum, and then applied it to Dirac RPA response and the present results for  $1^-$  and  $3^-$  longitudinal form factors. A comprehensive study of a full set of 18 response functions relevant to the  $(\vec{e}, e'p)$  reaction is presented by (1989PI07). (1988PR05) have studied the linear response of  $^{16}\text{O}$  to external electroweak current in a relativistic model. Hartree-Fock-RPA quasi-elastic cross sections for  $^{16}\text{O}(e, e'p)$  are calculated by (1989RY01), who also discuss final state interactions. Electromagnetic quasi-free proton knockout in a one-photon exchange approximation is studied in (1991BO10, 1991PA06). (1989RY06) performed self-consistent HF-RPA model calculations for  $(e, e'p)$  and  $(e, e'n)$  using Skyrme interactions in parallel and perpendicular kinematics. A consistent extension of the QHD1 mean-field RPA theory including correlations induced by isoscalar  $\sigma$  and  $\omega$  mesons of QHD1 is used by (1989SH27) to calculate  $(e, \tau')$  form factors and transition charge and current densities. See also (1991ZH17). (1986TK01) calculated M1 resonances taking  $1p-1h \times$  phonon excitations into account. Comparisons were made with data. (1987YO04) studied  $1\hbar\omega$  stretched excitations in configuration mixing calculations based on first-order perturbation theory.

#### 44. $^{16}\text{O}(\pi^\pm, \pi^\pm)^{16}\text{O}$

Angular distributions of elastically scattered pions have been studied at  $E_{\pi^-} = 20$  to 240 MeV and at 1 GeV/c as well as at  $E_{\pi^\pm} = 20$  to 315 MeV [see (1982AJ01, 1986AJ04)] and recently at  $E_{\pi^\pm} = 100$ –250 MeV at  $175^\circ$  (lab) (1987DH01), and at  $E_{\pi^-} = 30, 50$  MeV (1990SE04). At  $E_{\pi^\pm} = 164$  MeV,  $^{16}\text{O}^*(0, 6.1, 6.9, 7.1, 11.5, 17.8, 19.0, 19.8)$  are relatively strongly populated. The  $\pi^+$  and  $\pi^-$  cross sections to  $^{16}\text{O}^*(17.8, 19.8)$  [ $J^\pi = 4^-; T = 0$ ] are substantially different while those to  $^{16}\text{O}^*(19.0)[4^-; 1]$  are equal. Isospin mixing is suggested with off-diagonal charge-dependent mixing matrix elements of  $-147 \pm 25$  and  $-99 \pm 17$  keV (1980HO13). [See also Reaction 67,  $^{17}\text{O}(d, t)$ ]. The inelastic pion scattering is dominated by a single quasi-free pion-nucleon interaction mechanism at  $E_{\pi^+} = 240$  MeV (1983IN02): this is not the case at energies below the  $\Delta$ -resonance (114 and 163 MeV). For recent inelastic measurements see (1987BLZZ).

For a study of  $(\pi^+, 2p)$  and  $(\pi^\pm, pn)$  at  $T_{\pi^+} = 165$  MeV see (1986AL22), at  $T_{\pi^+} = 115$  MeV see (1992MA09). See also (1986KY1A, 1986KY1B). Pion absorption at  $T_{\pi^+} = 65$  MeV followed by multinucleon emission is reported by (1992BA31). For  $(\pi^+, \pi^0p)$  at  $T_{\pi^+} = 165$  and 245 MeV see (1986GI15, 1988HO1L, 1991HO03). For  $(\pi^+, \pi^-)$  and  $(\pi^-, \pi^+)$  at  $T_{\pi^+} = 180, 240$  MeV see (1989GR06). For  $(\pi^+, \pi^+\pi^-)$  at  $T_{\pi^+} = 280$  MeV see (1989GR05). See also (1987ME12, 1989ME10, 1990KO36).

A calculation of differential elastic cross sections in a local approximation to the delta-hole model is described in (1991GA07).

Optical-model calculations for pion scattering on  $^{16}\text{O}$  are discussed in (1990CA09, 1990LI10).

Table 16.27: Excited states of  $^{16}\text{O}$  from  $^{16}\text{O}(\text{p}, \text{p}')$ ,  $(\text{d}, \text{d}')$ ,  $(^3\text{He}, ^3\text{He}')$  and  $(\alpha, \alpha')$ <sup>a</sup>

#### 45. $^{16}\text{O}(\text{n}, \text{n}')^{16}\text{O}$

Angular distributions have been measured at  $E_{\text{n}}$  to 24 MeV [see (1982AJ01, 1986AJ04)] and recently at  $E_{\text{n}} = 18$  to 26 MeV (1987IS04, 1988MEZX); n's were observed leading to  $^{16}\text{O}^*(6.05, 6.13, 6.92, 7.12, 9.85, 10.35, 11.0, 11.52)$ . For small-angle measurements at  $E_{\text{n}} = 14.8$  MeV, see (1992QI02). Differential cross sections for  $(\text{n}, \text{n})$  and  $(\text{n}, \text{n}')$  at  $E_{\text{n}} = 21.6$  MeV are reported by

(1990OL01). Polarization of gamma rays from ( $n, n'$ ) with polarized neutrons to  $^{16}\text{O}^*(6.05, 6.13)$  was studied by (1988LI34) [see also (1987PO11)]. See also the evaluation of  $E_n = 10^{-5}$  eV–20 MeV neutron data for  $^{16}\text{O}$  in (1990SH1D).

The folding model has been used to calculate the nucleon– $^{16}\text{O}$  interaction potential, and the effect of different nucleon-nucleon forces has been discussed (1989HA24). See also the analysis with nonlocal potentials based on RGM formulations by (1992KA21) and the optical model study of (1992BO04). See also (1991KA19, 1991KA22, 1991SH08).

Angular distributions of elastically and inelastically scattered protons have been measured at many energies up to  $E_p = 1000$  MeV [see (1982AJ01, 1986AJ04)] and recently at  $E_p = 7.58$  MeV (1987KR19; p to  $^{16}\text{O}^*(6.05)$ ), 8.9–50 MeV, (1988LE08; p to  $^{16}\text{O}^*(6.129)$ ), 35 MeV, (1990OH04); p to  $^{16}\text{O}^*(E_x \leq 12.97)$ ), 40–85 MeV, (1987LA11; p to  $^{16}\text{O}^*(6.1299, 8.8719)$ ), 22, 35, 42 MeV, (1988SA1B; p to  $^{16}\text{O}^*(6.129)$ ), 135 MeV, (1986GA31; p to  $^{16}\text{O}^*(6.044, 7.117, 12.043)$ ), (1989KE03; p to  $^{16}\text{O}^*(6.049, 6.130, 6.917, 7.117, 9.847, 10.353, 11.09)$ ), 180 MeV, (1990KE03; p to  $^{16}\text{O}^*(E_x \leq 12.1)$ ), 200 MeV, (1986KIZW; p to  $^{16}\text{O}^*(10.957)$ ), (1989SAZZ; p to  $^{16}\text{O}^*(10.957, 12.797)$ ), 201 MeV. (1987DJ01; p to many states [see Table 16.27]), 320–800 MeV (1988BL07), 318 and 500 MeV, (1988FEZX, 1989FEZV, 1991FL01, 1991KE02), 100 and 200 MeV (1988SEZU, 1990GL09), 200, 318 MeV, (1990FEZY), 400 MeV (1991KI08), and 1000 MeV (1988BE2B). Parameters of the observed groups are displayed in Table 16.27. See also (1990OP01) and the analysis of (1990ER09).

For reaction (b) see (1991CO13; 151 MeV), (1986MC10; 505 MeV) and the review of (1987VD1A). For reaction (c) see (1986BO1A; 50 MeV), (1986SA24; 76.1, 101.3 MeV). For reaction (p,  $p\alpha$ ) see (1986VD04; 50 MeV). See also the study with antiproton beams of (1986KO22).

(1987CO25) have performed calculations using the Dirac equation for p and n distortions for the  $^{16}\text{O}(\vec{p}, n\pi^+)^{16}\text{O}$  reaction. A coupled-channels calculation using Dirac phenomenology for inelastic scattering of 800 MeV protons from  $^{16}\text{O}$  is presented in (1988DE35). (1988DE31) have studied the importance of a deformed spin-orbit potential in the calculations of (1988DE35). Approximate treatment of the nucleon-nucleus interaction in the resonating group method is discussed in (1991KA19). First order Kerman-McManus-Thaler optical potentials have been constructed from realistic meson-exchange models of N-N interaction including off-shell effects, and are found to be important for spin observables at 200–500 MeV (1989EL02). Optical phase shifts have been calculated to fifth order by (1988FR06), taking into account cm correlations. The significance of higher-order corrections is assessed. (1989GU06) consider breakup reactions in high temperature

plasmas, including production of 6.129 MeV  $\gamma$ 's from  $^{16}\text{O}$ : mainly from  $\text{p} + ^{16}\text{O} \rightarrow \text{p}' + ^{16}\text{O}^*$ ,  $\gamma + ^{16}\text{O} \rightarrow \gamma' + ^{16}\text{O}^*$ , and  $\text{p} + ^{20}\text{Ne} \rightarrow \text{X} + ^{16}\text{O}^*$ . (1988HA08) found Dirac optical potentials constrained by relativistic Hartree theory to give good agreement with elastic scattering data. See also (1990TJ01, 1991SH08). Spin observables have been calculated by (1988HO1K) for proton quasi-elastic scattering in the relativistic plane wave-impulse approximation, and compared to  $(\text{p}, \text{p}')$  data at 490 MeV. Isoscalar spin response functions are studied in (1990SH10). (1987KE1A) constructed a parametrization of medium modifications of the 2N effective interaction to reproduce nuclear matter theory, and adjusted it to reproduce proton inelastic scattering data. They obtained good fits to cross section and analyzing power for nine states simultaneously. (1989KE05) performed similar calculations, and fitted 135 MeV proton cross section and analyzing power data with the effective interactions. (1986KU15) performed a DWIA calculation of  $\sigma(\theta)$  and  $A_y(\theta)$  for  $^{16}\text{O}(\vec{\text{p}}, 2\text{p})$  at 200 MeV including spin-orbit and off-shell effects. (1987LU02) performed a semi-relativistic multiple scattering model calculation of intermediate energy proton elastic scattering, and investigated target nucleon correletion contributions. Multiple diffraction scattering theory was used to calculate cross sections and polarization observables in (1988BE57, 1991BE1E, 1991BE45, 1992BE03). See also (1991CH28, 1991CR04, 1992CR05). A Skyrme force approach was explored in (1988CH08). A scalar-vector form of a second-order relativistic impulse approximation optical model including dispersion effects was used by (1988LU03) to calculate elastic proton scattering at 500 and 800 MeV. Evidence for a small imaginary potential or actual flux emission was presented (1988MA05) for nucleon scattering from  $^{16}\text{O}$  at 30 MeV. As an alternate explanation of the (1988MA05) findings, (1988MA31) discuss the “ $\psi$ -potentials”, related to projectile current. (1988MA1X) contains a review of relativistic theory of nuclear matter and finite nuclei. A relativistic microscopic optical potential derived from the relativistic Brueckner-Bethe-Goldstone equation is discussed in (1992CH1E). Polarization transfer measurements in  $(\text{p}, \text{p}')$  reactions have been examined by (1986OR03) with regard to correlations of tensor character. (1986OS08) used the T-matrix approximation with distorted waves to analyze knock-off nucleon ( $\text{p}, \text{pN}$ ) and cluster ( $\text{p}, \text{pX}$ ) proton induced reactions from 30 to 100 MeV. The scattering of 500 MeV protons has been calculated by (1987OT02) using the Dirac equation with and without recoil corrections. Both cross section and spin observables are examined and compared to data. See also (1991KA22). (1988OT04) present systematics of Dirac impulse approximation for cross sections and spin observables in elastic p scattering at 200, 500, and 800 MeV. Results are compared to data. A mixed-density expansion of the off-diagonal density matrix is used by (1988PE09) to study the non-local knockout exchange amplitude for nucleon-nucleus scattering. (1987PI02) studied  $0^+ \rightarrow 0^-$  transitions by medium energy protons using the relativistic impulse approximation. (1989PI01) considered corrections arising from the energy dependence of the NN interaction, especially for  $0^+(\vec{\text{p}}, \vec{\text{p}}')0^-$  reactions. Relativistic and non-relativistic dynamical scattering models have been used by (1988RA02) to predict elastic scattering observables in the forward angle for  $\text{p} + ^{16}\text{O}$  at 500 and 800 MeV. See also (1990CO19, 1990RA12). (1989RA02) have obtained the leading three-body anti-symmetrization correction to nucleon-nucleus elastic scattering calculations using multiple scattering theory. Small effects are found at intermediate energies. Folding model potentials are used by (1986YA16) to perform a systematic analysis of proton elastic scattering from 65–200 MeV. See also (1990AR11, 1990CR02, 1990EL01, 1991AR11, 1991AR1K).

Effects of short-range correlations on the self energy in the optical model of  $^{16}\text{O}$  are studied in (1992BO04). See also (1992LI1D).

Angular distribution studies have been carried out for  $E_d$  up to 700 MeV [see (1986AJ04)] and recently angular distributions and analyzing powers with polarized deuterons were measured at 19–24 MeV (1991ER03) and at 200, 400, 700 MeV (1987NG01). Observed deuteron groups are displayed in Table 16.27. See also  $^{18}\text{F}$  in (1987AJ02), and see the analysis of (1990ER09).

Reaction (b) has been used for analysis of oxygen in Fluoride glasses (1990BA1M).

Coupled-channels variational formalism is discussed and applied to  $^{16}\text{O}(\text{d}, \text{d})^{16}\text{O}$  (1986KA1A). Coupling to the proton channel is significant at 11 MeV, but can be ignored at  $\geq 40$  MeV. Coupling to d-breakup channels decreases as  $E$  increases, but is still significant at 60 MeV. (1988IS02) use folding interactions to investigate polarized d-scattering at  $E_d = 56$  MeV. Breakup channels are important, as is the D-state admixture in the deuteron ground state — especially for tensor analyzing powers. (1988IS02) employed the continuum-discretized coupled-channels (CDCC) method, and obtained good agreement with data. (1987GR16) studied d-scattering at 400 MeV using the folding model, but failed to describe  $A_{yy}$  at relatively low momentum transfers. They attribute this failure to inadequacies in off-shell properties of N-N potentials. (1986MA32) analyzed elastic data at 56 MeV using an optical model potential containing a complex tensor term. The OM potential was compared with folding-model results. (1987MA09) evaluate the Pauli-blocking correction of the three-body Schrödinger equation for d-nucleus reactions.

Angular distributions are reported for  $E_t$  to 20.01 MeV: see (1977AJ02) and recently at 36 MeV (1986PE13, 1987EN06). See also  $^{19}\text{F}$  in (1987AJ02), and see the analysis of (1990ER09).

(1989WA26) studied the spin-orbit potential for triton scattering to explain previous discrepancies with folding model predictions.

Angular distributions have been measured to  $E(^3\text{He}) = 132$  MeV [see (1982AJ01, 1986AJ04)] and at  $E(^3\text{He}) = 60$  MeV (1990ADZU). The matter radius  $\langle r^2 \rangle^{1/2} = 2.46 \pm 0.12$  fm (1982VE13). Inelastic groups are shown in Table 16.27. See also the analysis of (1990ER09). Differential cross

sections for reaction (b) have been measured at  $E(^3\text{He}) = 60$  MeV ([1990ADZT](#)). The reaction has also been used in thin film analysis ([1990AB1G](#)).

([1986WA1U](#)) studied the spin-orbit potential for  $^3\text{He}$  scattering to explain previous discrepancies with folding model predictions. The M3Y double folding model is used ([1987CO07](#)) to fit data at 33 MeV. No change in the spin-orbit strength is necessary. The three-parameter strong absorption model of Trahn and Venter is applied to data at 25 and 41 MeV. ([1987RA36](#)) obtain radii, diffusivities and quadrupole deformation parameters. ([1987TR01](#)) perform a simple optical model analysis of elastic  $^3\text{He}$  scattering from 10 to 220 MeV.

- |  |                  |
|--|------------------|
| 50. (a) $^{16}\text{O}(\alpha, \alpha')^{16}\text{O}$    |                  |
| (b) $^{16}\text{O}(\alpha, \alpha\text{p})^{15}\text{N}$ | $Q_m = -12.127$  |
| (c) $^{16}\text{O}(\alpha, 2\alpha)^{12}\text{C}$        | $Q_m = -7.16195$ |

Angular distributions and/or differential cross sections of  $\alpha$ -particles have been measured up to  $E_\alpha = 146$  MeV [see ([1982AJ01](#), [1986AJ04](#))] and recently at  $E_\alpha = 48.7, 54.1$  MeV ([1987AB03](#);  $\alpha_0$ ): see  $^{20}\text{Ne}$  in ([1983AJ01](#), [1987AJ02](#)). See also the work on  $(\alpha, \alpha_0)$  resonances at  $E_\alpha = 2.0 - 3.6$  MeV ([1985JA17](#), [1988BL1H](#)). A search at  $E_\alpha = 10.2 - 18$  MeV for continuum levels in  $^{20}\text{Ne}$  with a large [ $^{16}\text{O}^*(0_2^+) + \alpha$ ] parentage is described in ([1992LA01](#)). Reaction (a) has also been observed in astrophysical measurements ([1989LA1G](#)). Observed excited states are displayed in Table 16.27. See also the analysis of ([1990ER09](#)), and see ([1990DA1Q](#), [1990IR01](#)).

Reaction (b) has been studied at  $E_\alpha = 13.92$  MeV in a quasifree geometry ([1987SA01](#)). Angular correlations (reaction (c)) have been studied to  $^{12}\text{C}_{\text{g.s.}}$  at  $E_\alpha = 23.0$  to 27.5 MeV to try to determine if a  $3^-$  state exists near the  $2^+$  state  $^{16}\text{O}^*(9.84)$ : the evidence is strong that this is not the case ([1986AJ04](#)). The isoscalar ( $E2, T = 0$ ) giant resonance decays predominantly via the  $\alpha_1$  channel which contains  $\sim 40\%$  of the E2 EWSR, rather than via the  $\alpha_0$  and  $p_0$  channels. For the  $(\alpha, \alpha\text{d})$ ,  $(\alpha, \alpha\text{t})$  and  $(\alpha, \alpha^3\text{He})$  reactions see references in ([1986AJ04](#)).

In a theoretical study of nucleus-nucleus potentials, ([1987BA35](#)) determine shallow potentials that are phase equivalent to deep ones. This method eliminates non-physical bound states encountered in some microscopically founded potentials. ([1987BU06](#)) calculate the probability of direct alpha-decay of the giant quadrupole resonance in  $^{16}\text{O}$ . They find direct and statistical mechanisms to be commensurate, and obtain good agreement with the data. The construction of a cranked cluster wave function for molecular-like states is discussed by ([1986HO33](#)). ([1986MA35](#)) study the radial shape and the energy dependence of the dispersive contribution to the real potential and apply it to alpha-particle scattering from  $^{16}\text{O}$ . ([1989MI06](#)) show that alpha-particle scattering from  $^{16}\text{O}$  near the Coulomb barrier can be described if the interaction is angular momentum dependent and has a less diffuse surface than that used to describe scattering at higher energies. The potential separable expansion method based on Coulomb-Sturmian functions is presented ([1988PA21](#)) and the  $l = 3$  phase shift is calculated for  $\alpha + ^{16}\text{O}$  at  $E = 12$  MeV. ([1987SA55](#)) show the one-channel orthogonality condition model provides results which agree with experiment for  $E_\alpha \leq 7.5$  MeV. ([1987WA1B](#)) compare a microscopic potential obtained from RGM calculations with the optical

model potential. They conclude that internucleus antisymmetrization is responsible for a large part of the energy dependence of the real part of OM potential. ([1989YA15](#), [1991YA08](#)) use the many body theory which takes the Pauli principle into account to calculate the  $\alpha$ - $^{16}\text{O}$  complex potential from a realistic effective two-nucleon interaction. The role of the Pauli principle is also examined in ([1991OM03](#)). Internucleus potentials in  $\alpha + ^{16}\text{O}$  systems are calculated with Skyrme-type forces in ([1990WA01](#)). Nuclear molecular resonances are discussed in the analyses of ([1990AB10](#), [1992SA26](#)). See also ([1990KR16](#)). A peripheral 3-body coupling model is applied to reaction (c) in ([1992JA04](#)).

51. (a)  $^{16}\text{O}(^6\text{Li}, ^6\text{Li})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^7\text{Li}, ^7\text{Li})^{16}\text{O}$

Elastic angular distributions for reaction (a) have been measured at  $E(^6\text{Li}) = 4.5$  to  $75.4$  MeV and  $E(^{16}\text{O}) = 36$  to  $94.2$  MeV [see ([1986AJ04](#)) and Tables 16.25 in ([1977AJ02](#)) and 16.23 in ([1982AJ01](#))] and recently at  $E(^6\text{Li}) = 50$  MeV ([1988TRZY](#)). See also ([1987GO1C](#)). Vector analyzing power has been measured with polarized  $^6\text{Li}$  beams at  $E(^6\text{Li}) = 25.7$  MeV ([1987VAZY](#), [1989VA04](#)). See also  $^6\text{Li}$  in ([1988AJ01](#)). For studies of d- $\alpha$  angular correlations see  $^{20}\text{Ne}$  in ([1983AJ01](#), [1987AJ02](#)). For a fusion cross section study see ([1986MA19](#)). Inelastic scattering to states in  $^{16}\text{O}$  are reported at  $E(^6\text{Li}) = 50$  MeV by ([1990TR02](#)).

Elastic distributions for reaction (b) have been studied at  $E(^7\text{Li}) = 9.0$  to  $68$  MeV [see ([1986AJ04](#)) and Tables 16.25 in ([1977AJ02](#)) and 16.23 in ([1982AJ01](#))] as well as at  $E(^7\text{Li}) = 10.3$ – $22.40$  MeV ([1988MA07](#)). For fusion cross section studies see ([1988SC14](#)) and references in ([1986AJ04](#)). See also ([1988KE07](#)).

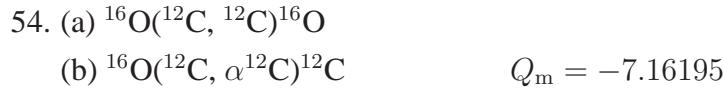

A generalized optical model within the method of orthogonal conditions (MOC) has been formulated by ([1988GR32](#)). Taking account of antisymmetrization improves the description of angular distribution data. See also ([1990SA1O](#)).

52.  $^{16}\text{O}(^9\text{Be}, ^9\text{Be})^{16}\text{O}$

Elastic angular distributions have been reported at  $E(^9\text{Be}) = 20$  to  $43$  MeV and  $E(^{16}\text{O}) = 15$  to  $29.5$  MeV [see ([1986AJ04](#)) and Table 16.23 in ([1982AJ01](#))] and recently at  $E_{\text{c.m.}} = 7.2$ ,  $8.4$ ,  $9.0$ ,  $9.6$ ,  $10.2$  MeV ([1989WE1I](#)). Projectile decomposition measurements were reported at  $E(^{16}\text{O}) = 32$  MeV/nucleon. For fusion cross sections see ([1982AJ01](#), [1986AJ04](#), [1988HAZS](#)). See also ([1985BE1A](#)).

53. (a)  $^{16}\text{O}(^{10}\text{B}, ^{10}\text{B})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{11}\text{B}, ^{11}\text{B})^{16}\text{O}$

Angular distributions have been reported at  $E(^{10}\text{B}) = 33.7$  to 100 MeV and at  $E(^{11}\text{B}) = 41.6$ , 49.5 and 115 MeV [see (1986AJ04) and Table 16.23 in (1982AJ01)] and recently at  $E_{\text{c.m.}} = 14.17$ , 16.15, and 18.65 MeV (1989KO10). See also (1989KO2A). For fusion cross section measurements (reaction (a)) see (1982AJ01, 1986AJ04).

Angular distributions have been reported at many energies to  $E(^{16}\text{O}) = 1503$  MeV [see (1982AJ01, 1986AJ04)] and recently at  $E(^{16}\text{O}) = 49.14, 48.14, 48.06$  MeV (1986BA80). A peak in the excitation function at  $E_{\text{c.m.}} = 33.5$  MeV was observed by (1990KO1X). See also the review of (1986BA1D) and analyses of (1988BR04, 1988RO01, 1989VI09). Many of the studies of this reaction have involved yield and cross section measurements, as they apply to compound structures in  $^{28}\text{Si}$ , fusion cross sections and evaporation residues. See (1990SN1A). Some involve multinucleon transfer. Others involve fragmentation of the incident particle. See (1982AJ01, 1986AJ04) and (1986GA13, 1986IK03, 1986SU1G, 1987SU03, 1988KO17, 1988SZ02, 1990BO1X). See also (1986CH41, 1986DE40, 1986SN1B, 1986WU03, 1987HO1C, 1987NA1C, 1987YO1A, 1988BR1N, 1988CAZV, 1988KR11, 1988ME1H, 1989BEZC, 1989KRZX, 1989SU1I, 1989WE1E, 1990BA1Z).

At  $E(^{16}\text{O}) = 100$  MeV members of the  $K^\pi = 0^+ [^{16}\text{O}^*(6.05, 6.92, 10.35, 16.3)]$  and  $K^\pi = 0^-$  bands [ $^{16}\text{O}^*(9.63, 11.60, 14.67)$ ] are reported to be preferentially populated. In reaction (b), as well as in the scattering of 140 MeV  $^{16}\text{O}$  on  $^{13}\text{C}$  and  $^{28}\text{Si}$ ,  $^{16}\text{O}^*$  states (9.83, 10.33, 11.04, 11.47, 11.98, 12.38, 13.81, 14.75, 15.33, 17.76), with  $J^\pi = 2^+, 4^+, 4^+, 2^+, 0^+, 1^-, 2^+, 4^+, 6^+, 3^-$ , respectively, for the first ten states, are populated: the state at 11.5 MeV is preferentially populated [see references in (1982AJ01, 1986AJ04)]. For pion emission see (1986AJ04, 1988SA31, 1989LE12).

(1987BA50) have investigated the two-proton correlation function using the BUU (semiclassical transport equations) model with conserved total momentum. Experimental features of the correlation function are reproduced. (1988BA43) study the energy dependence of the real part of the nucleus-nucleus potential using a modified Seyler-Blanchard two-body effective interaction containing density and momentum dependence. (1987BRZW) perform an optical model analysis of  $^{12}\text{C}-^{12}\text{C}$  and  $^{16}\text{O}-^{12}\text{C}$  elastic scattering from 10–94 MeV; real part: double folding of a density dependent M3Y interaction — imaginary part: phenomenological.

(1988BR20) examine dips in the far-side cross sections which reduce or eliminate potential ambiguities from analyses as in (1987BRZW). (1988BR29) analyzed elastic data at 9 to 120 MeV per nucleon using a folded potential based on the density and energy-dependent DDM3Y interaction. (1987DA02) present a solution to the inversion problem (i.e., obtaining potentials from data) and apply it to  $^{16}\text{O} + ^{12}\text{C}$  at 1503 MeV with good results. A microscopic calculation of pion-production in heavy-ion collisions is applied (1986DE15) to coherent pion-production in  $^{16}\text{O} + ^{12}\text{C}$  collisions. Effects of Pauli blocking and a surface contribution to the optical potential are investigated by (1989EL01). Data require that a collective surface contribution be added to the volume part.

(1988FR14) resolve optical potential model ambiguities by using dips in far side cross section data along with other special features of the angular distributions of elastic scattering data.

(1986HA13) performed a barrier penetration calculation of heavy-ion fusion cross sections, valid both above and below the Coulomb barrier. (1986KA1B) survey projectile breakup processes using the method of coupled discretized continuum channels. An optical model potential containing a parity dependence which accounts for elastic  $\alpha$ -particle transfer can explain the oscillations seen in the total fusion excitation function of  $^{16}\text{O}$  on  $^{12}\text{C}$  (1988KA13). (1988KO27) perform an optical model analysis of  $^{16}\text{O}$  scattering data at  $E/A = 94$  MeV. They explored potential shapes more general than folded or Woods-Saxon; no improvement in agreement with data. (1989LE23) analyzed reaction data using an eikonal approach. They input only the densities and transition densities of the nuclei and elementary nucleon-nucleon scattering amplitudes. Good agreement with data was obtained. The  $^{12}\text{C} + ^{16}\text{O}$  internucleus potential is calculated with the use of Skyrme type forces by (1990WA01).

(1989MI1K) calculate zero-degree and transverse energy for relativistic collisions. Results fit data very well. Low energy optical potentials are derived (1987PA24) from effective interactions using double-folding. Only the effective interaction of Satchler and Love give good results over a wide energy range. (1988RA1G) explores the relationship between clustering and shell effects, and find that this relationship is a close one. (1986SA1D) perform a microscopic coupled-channels calculation. Breakup and virtual breakup effects are found to be important. (1987SC34) present an expression for the real part of the nucleus-nucleus potential (energy dependent) which arises in the framework of the elastic model for heavy-ion fusion. This model is applied to sub-barrier fusion. (1988WU1A) propose a non-compact group model to describe quasi-molecular nuclei.

55. (a)  $^{16}\text{O}(^{13}\text{C}, ^{13}\text{C})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{14}\text{C}, ^{14}\text{C})^{16}\text{O}$

For elastic scattering studies see Table 16.23 in (1982AJ01), and see the more recent work at  $E_{\text{c.m.}} = 48.06, 48.48, 49.14$  MeV (1986BA80), and  $E_{\text{c.m.}} = 19\text{--}30$  MeV (1989FR04). For fusion cross sections see (1986AJ04) and recent work at  $E_{\text{c.m.}} = 7.8\text{--}14.6$  MeV (1986PA10). See also the review of (1986ST1A). For the excitation of a number of states in  $^{16}\text{O}$  in reaction (a) see (1986AJ04). Cross sections for different exit channels of  $^{16}\text{O} + ^{13}\text{C}$  at  $E_{\text{c.m.}} = 4.8\text{--}9.8$  MeV were measured by (1991DA05). Emission ratios for pn to d and  $\alpha$ pn to  $\alpha$ d were studied in (1986GA13). Competition between p2n, dn, and t emission was studied at  $E_{\text{c.m.}} = 10\text{--}16$  MeV (1990XE01). For reaction (b) a search for resonances in elastic scattering at  $E_{\text{lab}} = 38\text{--}54$  MeV is reported in (1990AB07).

(1987DA34) performed a six-parameter optical model analysis of  $^{13}\text{C}(^{16}\text{O}, ^{16}\text{O})^{13}\text{C}$ . A two-center shell model is applied (1987NU02) to the  $^{13}\text{C} + ^{16}\text{O}$  system. Parity dependence of collisions between p- and sd-shell nuclei is studied (1986BA69) microscopically in the two-center harmonic oscillator model.

56. (a)  $^{16}\text{O}(^{14}\text{N}, ^{14}\text{N})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{15}\text{N}, ^{15}\text{N})^{16}\text{O}$

For elastic scattering studies see (1986AJ04) and Table 16.23 in (1982AJ01) and (1977AJ02). Recent measurements on reaction (b) at  $E_{\text{lab}} = 30$ –70 MeV were reported in (1986HA1F). For yield and total fusion cross-section measurements see (1982AJ01, 1986AJ04). See also (1986BA69).

### 57. $^{16}\text{O}(^{16}\text{O}, ^{16}\text{O})^{16}\text{O}$

The angular distributions for elastic scattering have been measured with  $E(^{16}\text{O})$  up to 140.4 MeV [see (1982AJ01, 1986AJ04)] and recently at  $E_{\text{c.m.}} = 17$  MeV (1987TI01),  $E(^{16}\text{O}) = 350$  MeV (1989ST08) and  $E(^{16}\text{O}) = 38$  MeV/nucleon (1986BR25). Inelastic scattering studies involving  $^{16}\text{O}^*(6.05)$  [ $J^\pi = 0^+$ ] (1989ZUZZ) are reported at  $E(^{16}\text{O}) = 51.0$  to 76.0 MeV, and similar studies involving  $^{16}\text{O}^*(6.13)$  [ $J^\pi = 3^-$ ] (1988PAZZ) are reported at  $E_{\text{c.m.}} = 26.5$ –43.0 MeV. Coupled channels effects are important at energies a few times the Coulomb barrier (1977AJ02, 1986AJ04). Intermediate and compound structure studies are described in (1986GA10, 1986GA24).

For yield and fusion cross sections see (1982AJ01, 1986AJ04) and more recent work (1986IK03, 1986TH1A, 1987GO30, 1987KU02, 1988AU03). At  $E(^{16}\text{O}) = 72$  MeV, (1988AU1A) see no evidence for a low- $\ell$  fusion window. At  $E(^{16}\text{O}) = 70$ –130 MeV measurements of evaporation residues by (1986IK03) find no evidence for a low- $\ell$  cutoff. For a study of  $\alpha$ -transfer at near-barrier energies see (1986CA24). Light-particle emission at  $E(^{16}\text{O}) = 25$  MeV/nucleon was studied by (1986CH27). Related work includes an investigation of the role of isospin in the statistical decay of the GDR by (1986HA30) and the review of hot nuclear matter (1989SU1I). See also (1989FE1F, 1989SC1I).

(1988AS03) evaluate the influence of the Uehling potential on subbarrier fusion. (1987GO19) report a calculation of the fusion cross section using a classical microscopic equations of motion approach. (1987LO01) study the effect of elastic transfer process on sub-barrier fusion reactions between similar nuclei. (1987OH08) show that internal and barrier waves based on a semiclassical picture can account for the oscillations seen in fusion excitation functions. (1987RA28) use statistical theory to study the behavior of high spin states formed in fusion reactions. (1987SP11) calculate the fusion excitation function using the one-body wall friction.

(1987TO10) investigate the influence of nucleon-nucleon collisions in the low angular momentum limit for fusion predicted by TDHF. A relativistic mean-field model consisting of nucleons coupled to scalar and vector mesons is used to solve the time-dependent mean-field equations. A relativistic Vlasov equation derived from mean field theory is applied in (1990JI1C). An extended TDHF theory has been used (1989GO1F) to study mass fluctuations in deep-inelastic collisions. Results show differences from conventional TDHF calculations (1987BA10). (1988RE1A) performed TDHF calculations of  $^{16}\text{O} + ^{16}\text{O}$  using various Skyrme forces. (1986TO14) calculate subthreshold pion-production using the TDHF formalism, and compare their findings with data. (1986UM02) study fusion of  $^{16}\text{O} + ^{16}\text{O}$  using TDHF and Skyrme forces. See also the study of (1990SL01).

(1986CH44) perform an optical model analysis of elastic scattering data using a calculated real part of the potential. The potentials are constructed in the energy density formalism with nuclear density distributions obtained in the framework of the method of hyperspherical functions.

(1989DA1C) develop a simple theory of a heavy-ion optical model potential. Colliding ions are described as two slabs of nuclear matter, with energy densities from properties of nuclear matter. (1986FA1A) extend and refine the calculation of the real and imaginary parts of the optical model potential in the 20–100 MeV/nucleon range. Techniques for choosing a unique potential are discussed in (1990KO18). See also (1990RE1E). (1988NA10) calculate microscopic nucleus-nucleus potentials using the energy-density formalism. See also (1991MA29). (1987PA24) derive real parts of the low-energy optical potential using the double-folding model. Pauli exchange effects within this model are studied in (1991KH08). A semiclassical method for calculating elastic scattering cross sections was used in (1991SA20).

(1989HU1C) combine the concepts from a partition temperature model and the wounded nucleon model to describe high-energy nucleus-nucleus collisions. (1988IT03) have applied coupled equations which treat the relative motion and internal excitation simultaneously to the case of  $^{16}\text{O} + ^{16}\text{O}$  at intermediate energies. (1987KA04) study subthreshold pion production mechanisms for  $^{16}\text{O} + ^{16}\text{O}$  at 40 and 80 MeV/nucleon. A quantum transport equation with two-body collisions included via a relaxation-time method is applied to  $^{16}\text{O}-^{16}\text{O}$  collisions between 40 and 200 MeV/nucleon (1988KO02). (1988KO09) compare predictions of momentum dependence of nucleus-nucleus interactions deduced from various models. (1989KO23) describe resonant phenomena in  $^{16}\text{O} + ^{16}\text{O}$  in terms of an ion-ion potential. (1988MA10) solve the inverse scattering problem for fixed angular momentum using  $E$ -dependent phases and a Povzner-Levian representation of the wave function. Adiabatic bound and Gamow states have been calculated (1986MI22) in a realistic two-center potential. Specific results for a neutron in a  $^{16}\text{O} + ^{16}\text{O}$  potential are presented. (1985SH1A) develop a microscopic approach to describe elastic and inelastic cross sections. They employ the quasiparticle phonon model for heavy ions and resolve the “fusion-window-anomaly”. The resonating group method is used by (1988WA31) to investigate constituent components of the  $^{16}\text{O}-^{16}\text{O}$  exchange potential. A two-center shell model description is discussed in (1990KH04).

58. (a)  $^{16}\text{O}(^{17}\text{O}, ^{17}\text{O})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{18}\text{O}, ^{18}\text{O})^{16}\text{O}$

Angular distributions of elastically scattered ions have been studied at  $E(^{16}\text{O}) = 24, 28$  and  $32$  MeV and  $E(^{17}\text{O}) = 53.0$  to  $66$  MeV,  $E(^{17}\text{O}) = 22$  MeV (reaction (a)) and at  $E(^{16}\text{O}) = 24$  to  $54.8$  MeV and  $E(^{18}\text{O}) = 35$  to  $89.3$  MeV (reaction (b)) [see (1982AJ01, 1986AJ04)]. Yields and fusion cross sections are reported in (1982AJ01, 1986AJ04). See also the studies on light-particle emission ratios in these reactions (1986GA13, 1990XE01).

(1987IMZZ) have studied the effects of rotational couplings by using the rotating molecular orbitals model. (1987IM1C) develop and use a formalism for dynamical treatment of the molecular orbitals of valence nucleons in nucleus-nucleus collisions. (1988IM02) consider the role of rotational coupling interactions in the transition between nucleon molecular orbitals. (1987MA22) use the semiclassical approach including both one- and two-step contributions to calculate the two-particle elastic transfer reaction, while (1988KA39) calculate differential cross sections for transfer

of two neutrons taking Coulomb effects into account in a four-body model. (1986MI22) use a realistic two-center potential to show that a substantial fraction of the particle emission comes from sequential decay of the excited fragments after separation, and (1986VI08) consider two-particle exchange reactions using a parity-dependent optical potential.

59. (a)  $^{16}\text{O}(^{19}\text{F}, ^{19}\text{F})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{20}\text{Ne}, ^{20}\text{Ne})^{16}\text{O}$

Elastic scattering angular distributions have been studied at  $E(^{16}\text{O}) = 21.4$  and  $25.8$  MeV and at  $E(^{19}\text{F}) = 33$  and  $36$  MeV: see (1977AJ02). Angular distributions in reaction (b) have been measured at  $E(^{16}\text{O}) = 40.7$  to  $94.8$  MeV,  $25.6$  to  $44.5$  MeV,  $44.1$  to  $63.9$  MeV [see (1986AJ04)],  $60$ – $80$  MeV (1986FUZV), and at  $E(^{20}\text{Ne}) = 50$  MeV (1986AJ04). Recent excitation functions were measured for reaction (b) at  $E_{\text{c.m.}} = 21.5$ – $31.2$  MeV (1988HE06). See also (1989SA14). For yield and fusion cross section measurements see (1986AJ04). Projectile breakup studies are reported at  $3.6$  GeV/nucleon. See also (1987AN1C). Hyperon production is investigated in (1986FUZV, 1988BO46). See also (1986HE1A, 1988BE2A).

(1986FU1C) discuss ways of accounting for the phase anomaly between elastic and inelastic scattering of  $^{19}\text{F} + ^{16}\text{O}$ . (1989GA05) derive a parity-dependent potential for  $^{16}\text{O} + ^{20}\text{Ne}$ .

60. (a)  $^{16}\text{O}(^{23}\text{Na}, ^{23}\text{Na})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{24}\text{Mg}, ^{24}\text{Mg})^{16}\text{O}$   
 (c)  $^{16}\text{O}(^{25}\text{Mg}, ^{25}\text{Mg})^{16}\text{O}$   
 (d)  $^{16}\text{O}(^{26}\text{Mg}, ^{26}\text{Mg})^{16}\text{O}$

Elastic angular distributions are reported at  $E(^{16}\text{O}) = 35$  to  $60.7$  MeV (reaction (b)) and  $27.4$  to  $50$  MeV (reaction (d)) [see (1982AJ01)] and  $E(^{16}\text{O}) = 150$  MeV (1986AJ04; reaction (b); elastic). More recent work on reaction (b) includes elastic scattering excitation function measurements at  $E_{\text{c.m.}} = 31.6$ – $45.2$  MeV (1986DR11, 1986DR1B) and inelastic measurements at  $E_{\text{c.m.}} = 33.6$ – $49.2$  MeV (1986NU01, 1986NU1A) and at  $E_{\text{c.m.}} = 64$ – $88$  MeV (1986PE1G). Orbiting cross sections for reaction (b) are reported in (1989BLZZ). For yield, evaporation residue and fusion measurements, see references in (1982AJ01, 1986AJ04).

(1988AL06) show that algebraic scattering theory provides a simple yet detailed description of the complex coupled channels problem ( $^{16}\text{O} + ^{24}\text{Mg}$ ). (1989FI03) calculate the effect of the dynamic  $\alpha$ -transfer potential on several channels of the  $^{24}\text{Mg} + ^{16}\text{O}$  systems. (1987NA13) obtain an energy and angular momentum-dependent polarization potential from a compound nucleus level density dependent imaginary potential. They find that the elastic and fusion cross sections of  $^{16}\text{O} + ^{24}\text{Mg}$  are hardly affected by this potential.

61.  $^{16}\text{O}(^{27}\text{Al}, ^{27}\text{Al})^{16}\text{O}$

An elastic angular distribution has been measured at  $E(^{16}\text{O}) = 46.5$  MeV: see (1982AJ01). For yield, fusion and evaporation residue studies see (1982AJ01, 1986AJ04) and (1987IK01, 1988KO01, 1989CA14, 1989DE02, 1990KR1D). See also (1986BR26, 1987DEZV). For fragmentation studies see (1986AJ04) and (1986SH1F, 1987SH1C, 1987SH23, 1988AI1C, 1988BR1N, 1988SH1H, 1989CA14, 1989YI1A, 1990PAZW). For work on deeply inelastic collisions see (1986AJ04) and (1987SH21). For pion production see (1986AJ04) and (1987HU1C, 1988BA21, 1988JU02, 1989FO07). For total reaction cross sections see (1987KO12). Angular correlations have been studied at  $E(^{16}\text{O}) = 65\text{--}65.6$  MeV (1986AJ04) and at  $E(^{16}\text{O}) = 82.7$  MeV (1988SH1H), at 215 MeV (1990KR14), at  $E_{\text{c.m.}} = 80\text{--}250$  MeV (1988DE1A, 1989DE02), and at  $E(^{16}\text{O}) = 4\text{--}5$  MeV/nucleon (1987CA1E). The sequential decay of  $^{16}\text{O}^*(10, 11.6, 13.2, 15.2, 16.2, 21)$  is reported via  $\alpha_0$  [see (1986AJ04)].

(1987BA01) evaluate the energy dependence of the real part of the nucleus-nucleus potential using two-body effective interactions, calculate  $^{16}\text{O} + ^{27}\text{Al}$ , and compare to data. (1989CA11) introduce “pre-equilibrium” temperature to describe the thermodynamics of nuclear systems prior to equilibrium. (1988DA11) modify the coalescence model for complex-particle emission by correcting for the Coulomb barrier and the ejectile’s binding energy.

62. (a)  $^{16}\text{O}(^{28}\text{Si}, ^{28}\text{Si})^{16}\text{O}$   
(b)  $^{16}\text{O}(^{29}\text{Si}, ^{29}\text{Si})^{16}\text{O}$   
(c)  $^{16}\text{O}(^{30}\text{Si}, ^{30}\text{Si})^{16}\text{O}$   
(d)  $^{16}\text{O}(^{31}\text{P}, ^{31}\text{P})^{16}\text{O}$

Angular distributions for reaction (a) have been reported at  $E(^{16}\text{O}) = 29.3$  to 215.2 MeV [see (1982AJ01, 1986AJ04)], and recently at  $E(^{16}\text{O}) = 94$  MeV/nucleon (1987RO04). Elastic angular distributions for reactions (b) and (c) are reported at  $E(^{16}\text{O}) = 60$  MeV (1986AJ04). For yield, fusion cross section and evaporation residue measurements see (1982AJ01, 1986AJ04). See also (1986BL08). For a crystal-blocking measurement of time delays in reaction (a) see (1989MA23). For pion production see (1986AJ04).

(1988AL08) obtain expressions for the elastic  $S$ -matrix which include effects of the coupling to  $\alpha$ -transfer channels to all orders. They study  $^{16}\text{O} + ^{28}\text{Si}$  at  $180^\circ$ . (1988AS03) evaluate the influences of the Uehling potential on sub-barrier fusion and obtain noticeable modifications of the barrier penetrability. (1986BR11) study the  $E$ -dependence of an optical potential which fits all  $^{16}\text{O} + ^{28}\text{Si}$  elastic data for  $E = 54.7\text{--}215.2$  MeV. (1986HO18) employ a fixed energy potential inversion method to generate an optical model potential which fits  $^{16}\text{O} + ^{28}\text{Si}$  elastic scattering data at 34.8 MeV. (1986BR19) create a deformed optical potential consistent with calculations based on nuclear structure information which fits  $^{16}\text{O} + ^{28}\text{Si}$  scattering and fusion data. (1986BR23) use an optical model with repulsive core and coupled channels method to describe  $^{16}\text{O} + ^{28}\text{Si}$  scattering data at large angles for  $E = 29\text{--}35$  MeV. (1988CH28) use a Monte Carlo simulation to calculate the

nucleon transfer part of the imaginary optical-model potential. (1987HU11) find good agreement with back angle elastic data in  $^{16}\text{O} + ^{28}\text{Si}$  by including a derived  $\alpha$ -transfer polarization potential. (1990DE35) employ a multistep  $\alpha$ -transfer treatment to study back angle scattering of  $^{16}\text{O} + ^{28}\text{Si}$ . (1985KH10) use a conventional optical model potential for  $E_{\text{lab}} = 33.16\text{--}55$  MeV. They parameterize the  $S$ -matrix in terms of Regge poles and look at semiclassical features. (1985KR1A) show that existing data do not allow one to draw conclusions about the relevance of Regge poles in  $^{16}\text{O} + ^{28}\text{Si}$ . (1989MA08) use elastic phase shifts obtained by the algebraic approach to scattering theory in a fixed energy inversion procedure. Results point to an underlying nonlocal interaction. (1987NA13) show that the elastic and fusion cross sections are hardly affected by a strongly attractive real-polarization-potential. (1987VA03) have applied a fast algorithm-based method for performing unconstrained phase-shift analyses to  $^{16}\text{O} + ^{28}\text{Si}$  at 21.1 MeV ( $E_{\text{c.m.}}$ ). (1987XI01) formulate a molecular orbit theory for the  $3\alpha$ -transfer process and apply it to  $^{16}\text{O} + ^{28}\text{Si}$  for  $E = 18.67\text{--}34.80$  MeV, and compare it to data.

63. (a)  $^{16}\text{O}(^{40}\text{Ca}, ^{40}\text{Ca})^{16}\text{O}$   
 (b)  $^{16}\text{O}(^{42}\text{Ca}, ^{42}\text{Ca})^{16}\text{O}$   
 (c)  $^{16}\text{O}(^{44}\text{Ca}, ^{44}\text{Ca})^{16}\text{O}$   
 (d)  $^{16}\text{O}(^{48}\text{Ca}, ^{48}\text{Ca})^{16}\text{O}$   
 (e)  $^{16}\text{O}(^{48}\text{Ti}, ^{48}\text{Ti})^{16}\text{O}$

Elastic angular distributions are reported on  $^{40}\text{Ca}$  at  $E(^{16}\text{O}) = 50$  to 214.1 MeV [see (1982AJ01, 1986AJ04) and recently at  $E(^{16}\text{O}) = 94$  MeV/nucleon (1988RO01). Elastic angular distributions were reported at  $E(^{16}\text{O}) = 60$  MeV ( $^{42,44}\text{Ca}$ ; also inelastic distributions) and 150 MeV [see (1986AJ04)]. Similar measurements have been reported for  $^{48}\text{Ca}$  at  $E(^{16}\text{O}) = 60$  MeV [see (1982AJ01)] and at 56 MeV (1986AJ04; also  $^{48}\text{Ca}^*$ ) and 158.2 MeV (1986AJ04; also  $^{48}\text{Ca}^*$ ). Yield, fusion cross section and evaporation residue measurements are reported in (1982AJ01, 1986AJ04) and by (1986SA25, 1987BEZY, 1987BR20, 1987HI10, 1988KO1U, 1989BE17). See also (1986GU1C). For a measurement of the total non-fusion reaction cross section at  $E(^{16}\text{O}) = 158.2$  MeV (reaction (d)) see (1986AJ04). For a study of deep inelastic collisions at 142 MeV (reaction (d)) and for reaction (e) see (1986AJ04).

A microscopic study of the  $^{16}\text{O} + ^{40}\text{Ca}$  potential is discussed in (1986WAZM). (1986AN18) calculate angular distributions for elastic scattering using a simple prescription for the part of the imaginary potential arising from inelastic processes and a folding expression for the real part of the potential, and fit it to the data. (1986CH20) perform a microscopic optical model analysis using folding and realistic NN interactions (direct and exchange terms). They compare their results to data. (1986CH38) calculate the real part of the optical model potential in a folding approximation using the density dependent M3Y interaction in factorized form. They also compare their results to data. (1989DA1C) describe colliding nuclei as two slabs of nuclear matter. Energy density is derived from properties of nuclear matter. (1989ES07) obtain good agreement with elastic and inelastic data using a coupled-channels treatment. (1987GR04) study peripheral reactions. Neutrons

and protons behave separately in an effective mean field. They find a transition between incomplete deep inelastic processes and fragmentation reactions near 35 MeV/nucleon. ([1986HA13](#)) calculate barrier penetrations with Coulomb included. They obtain good agreement with data in the above and sub-barrier fusion regions. ([1989HO10](#)) calculated heavy-ion fusion reactions with a macroscopic model proposed by Bertsch. They give a good account of the fusion cross section up to very high energies. ([1987DA23](#)) develop a semi-microscopic model of elastic and inelastic scattering with a full finite range NN interaction. They also study the role of NN exchange correlations. The real and imaginary potentials have been derived ([1987VI04](#)) in a model which includes a large set of non-elastic channels. ([1988PA20](#)) calculate the particle transfer flux between two scattering nuclei from the time-dependent single-particle wave functions in the field of two moving potential pockets. They deduce the absorptive potentials which compare well with phenomenological ones. ([1989SU05](#)) study the excitation of the GDR within the framework of the Landau-Vlasov equation. They analyze the GDR excited in peripheral  $^{16}\text{O} + ^{40}\text{Ca}$  reactions at  $E = 5$  MeV/nucleon.

The beta-delayed proton emission in the  $^{17}\text{Ne}$  decay has been studied by ([1988BO39](#)). See Tables [17.16](#) and [17.27](#). The half life is measured to be  $T_{1/2} = 109.3 \pm 0.6$  ms.

See ([1986AJ04](#), [1989OR07](#), [1990MC06](#)) and  $^{17}\text{O}$ .

Angular distributions for the ground state deuteron group have been studied at  $E_p = 8.62$  to 11.44 MeV. At  $E_p = 31$  MeV, angular distributions are reported for the deuterons corresponding to  $^{16}\text{O}^*(0, 6.05 + 6.13, 7.12, 8.87, 10.36, 12.97, 13.26)$ . States at  $E_x = 15.22$  and 15.42 MeV were also observed. Spectroscopic factors were obtained from a DWBA analysis: see ([1977AJ02](#), [1986AJ04](#)). See also ([1989DE1P](#), [1989OB1B](#)).

Differential cross sections and analyzing powers for the reaction were measured at  $E_d = 89$  MeV by ([1990SA27](#)) and summarized in Table [16.28](#). Earlier information obtained at  $E_d = 52$  MeV is displayed in Table 16.20 of ([1986AJ04](#)). As discussed there, comparison of the (d, t)

and (d,  $^3\text{He}$ ) reactions leads to assignments of analog states in  $^{16}\text{N}$  and in  $^{16}\text{O}$  [see Table 16.10 in (1982AJ01)]. A study of this reaction, the (d,  $^3\text{He}$ ) reaction, and reaction 67 [ $^{17}\text{O}(^3\text{He}, \alpha)^{16}\text{O}$ ] below, suggests that there is more than 17% isospin mixing of the  $2^-$  states in  $^{16}\text{O}^*(12.97, 12.53)$ : the corresponding mixing matrix element is  $\geq 155 \pm 30$  keV. An isospin mixing matrix element of  $110 \pm 10$  keV for the  $4^-$  states of  $^{16}\text{O}^*(17.79, 18.98, 19.80)$  is compatible with the results from this reaction and with pion scattering (1986AJ04). See also reaction 44 [ $^{16}\text{O}(\pi^\pm, \pi^\pm)^{16}\text{O}$ ].

Angular distributions have been reported at  $E(^3\text{He}) = 11$  MeV [see (1977AJ02)], at  $E(^3\text{He}) = 14$  MeV ( $\alpha_0$ ) and at  $E(^3\text{He}) = 33$  MeV (to many states of  $^{16}\text{O}$ ) [see (1986AJ04)]. Table 16.28 displays some of the information derived from this reaction. For polarization measurements see (1986AJ04) and  $^{20}\text{Ne}$  in (1983AJ01, 1987AJ02). See also (1982AJ01).

See (1986AJ04).

Angular distributions of tritons have been measured for  $E_p = 43.7$  MeV [see (1982AJ01)] and at  $E_p = 90$  MeV (1986VO10) (to  $^{16}\text{O}^*(6.1, 6.92, 7.12, 9.84, 13.26, 16.35)$ ): see also (1985BLZY). It is noted in (1986VO10) that the 16.35 MeV state may be the  $(0^+, 1^-, 2^+)$  multiplet at  $E_x = 16.35$  and 16.144 MeV (1982AJ01). The population of  $^{16}\text{O}^*(22.7, 24.5)$  is consistent with  $L = 0$  and 2, respectively, and with assignments of  $T = 2$ ,  $J^\pi = 0^+$  and  $2^+$ . The decay of  $^{16}\text{O}^*(22.7)$ ,  $J^\pi; T = 0^+; 2$ , is via  $\alpha_0$ ,  $\alpha_1$  and  $\alpha_2$  [ $^{12}\text{C}^*(0, 4.4, 7.7)$ ] with  $(1.6 \pm 0.7)$ ,  $(1.9 \pm 0.7)$  and  $(14 \pm 2)\%$  branches and  $\Gamma_i(\text{eV}) = 190 \pm 100$ ,  $230 \pm 110$  and  $1680 \pm 550$  eV, respectively; via  $p_0$ ,  $p_{1+2}$ ,  $p_3$  with  $(7 \pm 2)$ ,  $(11 \pm 2)$  and  $(5 \pm 2)\%$  branches and  $\Gamma_i(\text{eV}) = 840 \pm 343$ ,  $1320 \pm 454$  and  $600 \pm 300$  eV; and via  $n_{1+2}$  with a  $(23 \pm 15)\%$  branch [ $\Gamma_n = 2760 \pm 1970$  eV] (the  $n_0$  branch is  $< 15\%$ ) [ $\Gamma_i$  are based on a total width of  $12 \pm 3.5$  keV]. See (1986AJ04). See also (1982AJ01) and  $^{19}\text{F}$  in (1987AJ02).

Angular distributions have been measured at  $E_\alpha = 58$  MeV to  $^{16}\text{O}^*(0, 6.1, 6.92, 7.12)$ . Groups at  $E_x = 10.4$ ,  $13.3 \pm 0.1$  and  $16.3 \pm 0.1$  MeV were also observed: see (1977AJ02, 1986AJ04).

Table 16.28: States in  $^{16}\text{O}$  from  $^{17}\text{O}(\text{d}, \text{t})$  and  $^{17}\text{O}(^3\text{He}, \alpha)$

<sup>a</sup>  $^{17}\text{O}(\text{d}, \text{t})$ ;  $E_{\text{d}} = 89 \text{ MeV}$  ([1990SA27](#)).

<sup>b</sup> See Table 16.20 ([1986AJ04](#)).

<sup>c</sup>  $^{17}\text{O}(^3\text{He}, \alpha)$ ;  $E(^3\text{He}) = 11 \text{ MeV}$  ([1971BO02](#)).

<sup>d</sup>  $^{17}\text{O}(^3\text{He}, \alpha)$ ;  $E(^3\text{He}) = 33 \text{ MeV}$  ([1982KA12](#)).

Angular distributions involving  $^{16}\text{O}_{\text{g.s.}}$  and  $^{20}\text{O}$  states are reported at  $E(^{18}\text{O}) = 24$  to 36 MeV and at 52 MeV: see ([1982AJ01](#), [1986AJ04](#)).

Angular distributions have been measured at many energies up to  $E_p = 44.5$  MeV [see ([1982AJ01](#))] and  $E_p = 1.55$  to 2.03 MeV ( $\alpha_0, \alpha_1$ ), 1.66 to 1.86 MeV ( $\alpha_0$ ), 10.0 to 11.4 MeV ( $^{16}\text{O}^*(0, 6.05, 6.13, 6.92, 7.13, 8.87, 9.84, 10.36, 10.96, 11.08 + 11.10)$ ) [see ([1986AJ04](#))]. See also Table 16.31 in ([1971AJ02](#)). For a DWBA analysis of data for incident energies below the Coulomb barrier see ([1991HE16](#)). A recent measurement of the absolute differential cross section at  $E_p = 2$ –3.4 MeV is reported in ([1986OU01](#)). Measurements at  $E_p = 1.55$ –1.64 MeV by ([1990AZZY](#)) were used to study resonances corresponding to states in  $^{20}\text{Ne}$ . Absolute yields, angular distributions and resonance widths of the 6.13, 6.92, and 7.12 MeV photons from the 340.5 keV resonance are reported in ([1991CR06](#)). See also ([1991MC08](#)) for a study of resonance-yield deconvolution techniques.

The internal conversion to pair production ratio of the E0 transition  $^{16}\text{O}^*(6.05 \rightarrow \text{g.s.})$  [ $0^+ \rightarrow 0^+$ ] is  $(4.00 \pm 0.46) \times 10^{-5}$ . The ratio of double  $\gamma$ -emission to pair production  $\Gamma_{\text{E1E1}}/\Gamma_{\text{E0}(\pi)} = (2.5 \pm 1.1) \times 10^{-4}$ .  $\tau_m$  for  $^{16}\text{O}^*(6.05, 6.13)$  are  $96 \pm 7$  psec and  $26.6 \pm 0.7$  psec, respectively. See ([1982AJ01](#)) for references.  $|g|$  for  $^{16}\text{O}^*(6.13) = 0.556 \pm 0.004$  ([1984AS03](#), [1986AJ04](#)). For  $\gamma$ -ray branching ratios and mixing ratios see Table 16.14 and ([1986AJ04](#)).

See also  $^{20}\text{Ne}$  in ([1983AJ01](#), [1987AJ02](#)), and see ([1986KH1A](#), [1987KH1A](#), [1988GN1A](#), [1988UM1A](#); applied) and ([1988CA26](#); astrophysics).

Differential cross section measurements at  $E_t = 38$  MeV are reported in ([1992CL04](#)).

See ([1977AJ02](#)).

See ([1988SH1E](#)).

77. (a) $^{20}\text{Ne}(\gamma, \alpha)^{16}\text{O}$	$Q_m = -4.734$

The ground state angular distribution has been studied at  $E(^{12}\text{C}) = 40$  MeV [see ([1986AJ04](#))].  $^{16}\text{O} + ^8\text{Be}$  breakup of  $^{24}\text{Mg}$  following inelastic scattering of  $^{24}\text{Mg}$  projectiles on  $^{12}\text{C}$  has been reported ([1989FU10](#)).

83. $^{28}\text{Si}(^{12}\text{C}, ^{24}\text{Mg})^{16}\text{O}$	$Q_m = -2.822$
--	----------------

Forward-angle yields of  $^{16}\text{O}$  measured at  $E(^{28}\text{Si}) = 100 - 170$  MeV have been reported ([1986SH25](#)).

84. $^{28}\text{Si}(^{14}\text{N}, ^{16}\text{O})^{26}\text{Al}$	$Q_m = -1.682$
--	----------------

Forward-angle yields of  $^{16}\text{O}$  measured at  $E(^{28}\text{Si}) = 100 - 170$  MeV have been reported ([1986SH25](#)).

**$^{16}\text{F}$**   
 (Figs. 4 and 5)

GENERAL: See Table 16.29.

- |  |                |
|--|----------------|
| 1. (a) $^{14}\text{N}(\text{He}^3, \text{n})^{16}\text{F}$ | $Q_m = -0.957$ |
| (b) $^{14}\text{N}(\text{He}^3, \text{np})^{15}\text{O}$   | $Q_m = -0.421$ |

Observed neutron groups from reaction (a) and results from reaction (b) are displayed in Table 16.31. A recent measurement of n-p angular correlations from  $^{14}\text{N}(\text{He}^3, \text{n})^{16}\text{F}(\text{p})^{15}\text{O}$  is reported in (1986RYZZ).

- |  |                   |
|--|-------------------|
| 2. $^{15}\text{N}(\text{p}, \pi^-)^{16}\text{F}$ | $Q_m = -142.3475$ |
|--|-------------------|

Measurements of pion spectra with polarized protons at  $E_p = 200$  MeV are reported in (1987AZZY). Levels in  $^{16}\text{F}$  at 0.39 ( $2^-$ ), 0.72 ( $3^-$ ), 5.40, 6.37 ( $4^-$ ), 7.85, and 11.52 MeV are observed.

- |  |                  |
|--|------------------|
| 3. $^{16}\text{O}(\gamma, \pi^-)^{16}\text{F}$ | $Q_m = -154.984$ |
|--|------------------|

Angular distributions and photoproduction cross sections vs. energy have been measured for  $E_p = 200\text{--}350$  MeV (1987JE02). See also (1986AJ04).

- |   |                 |
|---|-----------------|
| 4. $^{16}\text{O}(\text{p}, \text{n})^{16}\text{F}$ | $Q_m = -16.199$ |
|---|-----------------|

Observed neutron groups are displayed in Table 16.31. Angular distributions of cross sections and/or polarization observables have been studied at  $E_p = 35\text{--}135.2$  MeV (1986AJ04) and recently at  $E_p = 35$  and 40 MeV (1987OH04) and at  $E_p = 135$  MeV (1989WAZZ). See also (1983WA29). For a comparison of (p, n) cross sections with B(M1) see (1986AJ04). A study of Gamow-Teller strengths is described in (1988MA53). An investigation of  $0^+ \rightarrow 0^-$  transitions is discussed in (1986GA31). See also (1989GA26) and the reviews of (1986AN1E, 1986BA78).

- |  |                 |
|--|-----------------|
| 5. $^{16}\text{O}(\text{He}^3, \text{t})^{16}\text{F}$ | $Q_m = -15.436$ |
|--|-----------------|

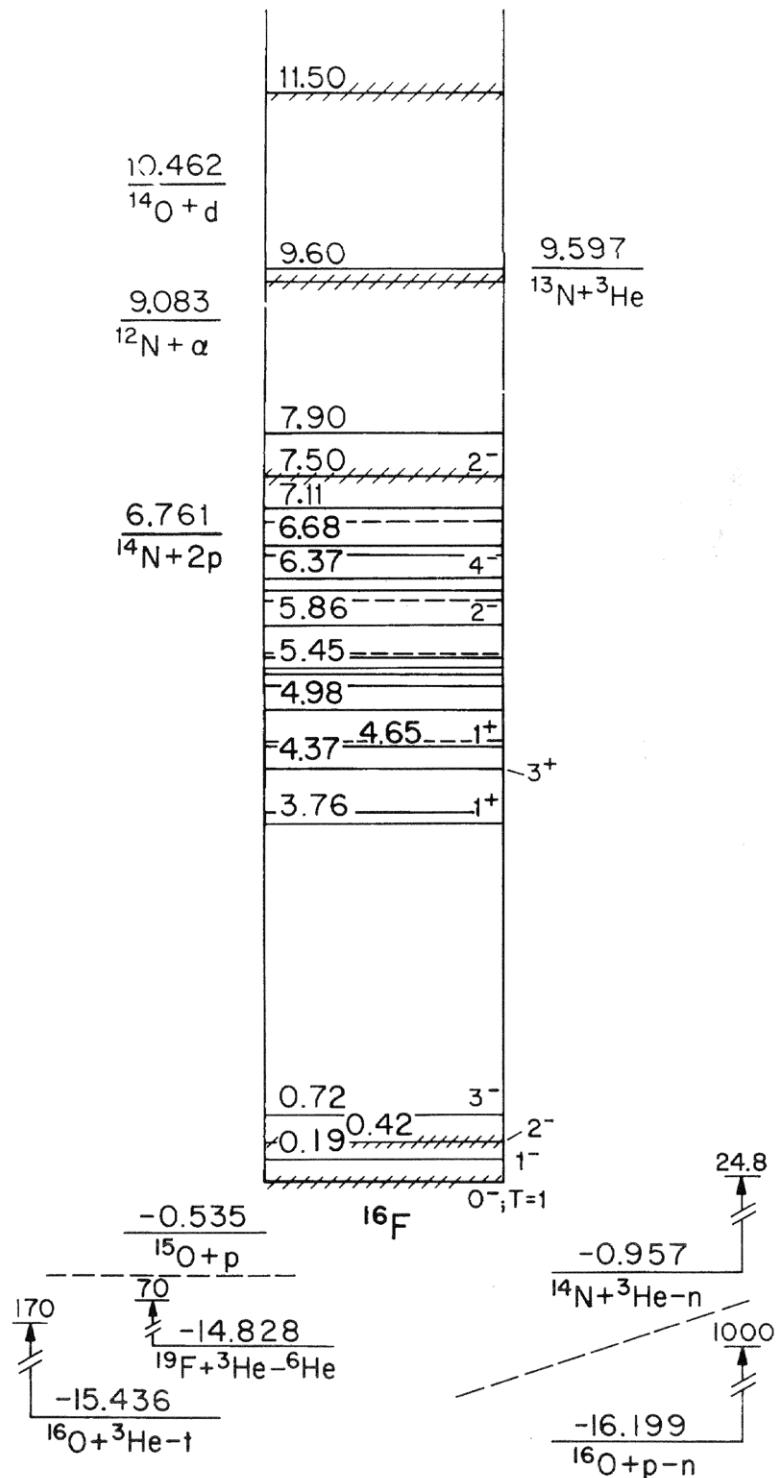

Fig. 4: Energy levels of  $^{16}\text{F}$ . For notation see Fig. 2.

<sup>h</sup>  $^{16}\text{O}(\text{He}^3, \text{t})$ : ([1984ST10](#);  $E(\text{He}^3) = 81$  MeV). See ([1986AJ04](#)).

<sup>i</sup> From (a) and ([1984ST10](#), [1985HA01](#)).

<sup>j</sup> From (a) and ([1984ST10](#)).

<sup>k</sup> See also ([1985HA01](#)).

<sup>l</sup> ([1985HA01](#)).

<sup>m</sup> Observed only in  $^{19}\text{F}(\text{He}^3, \text{He}^6)$ .

<sup>n</sup> Decays to  $^{15}\text{O}_{\text{g.s.}}$  by proton emission ([1984ST10](#)).

<sup>o</sup> Decays to  $^{15}\text{O}^*(6.18)$  ([1984ST10](#)).

Observed triton groups are shown in Table 16.31. Angular distributions at  $E(^3\text{He}) = 81$  MeV, analyzed by DWBA, and angular correlation measurements [mainly involving protons to  $^{15}\text{O}^*(0, 6.18)$ ], together with information from reactions 1 and 4, lead to the  $J^\pi$  values shown in the table. The analog of the giant dipole resonance [ $E_x \approx 9.5$  MeV] is strongly excited. The magnetic quadrupole strength has two strong components in  $^{16}\text{F}^*(0.42, 7.5)$ . The  $4^-$  state at 6.4 MeV and the GDR have also been observed at  $E(^3\text{He}) = 170$  MeV [see (1982AJ01, 1986AJ04)]. A recent measurement of differential cross sections at  $E(^3\text{He}) = 66\text{--}90$  MeV and DWBA analysis is reported in (1989VA09). See also (1985VA1A, 1990VA08).

6. (a) $^{16}\text{O}(^6\text{Li}, ^6\text{He})^{16}\text{F}$	$Q_m = -8.924$
(b) $^{16}\text{O}(^7\text{Li}, ^7\text{He})^{16}\text{F}$	$Q_m = -26.62$

Measurements have been reported at  $E(^6\text{Li}) = 93$  MeV,  $E(^7\text{Li}) = 78$  MeV [see (1986AJ04)]. See also (1989GA26).

7. $^{19}\text{F}(^3\text{He}, ^6\text{He})^{16}\text{F}$	$Q_m = -4.828$
---	----------------

See Table 16.31 and (1982AJ01, 1986AJ04).

### $^{16}\text{Ne}$ (Fig. 5)

GENERAL: See Table 16.29.

Mass of  $^{16}\text{Ne}$ : The  $Q$ -values of the  $^{20}\text{Ne}(\alpha, ^8\text{He})$  and  $^{16}\text{O}(\pi^+, \pi^-)$  reactions lead to atomic mass excesses of  $23.93 \pm 0.08$  MeV (1978KE06),  $23.978 \pm 0.024$  MeV (1983WO01) and  $24.048 \pm 0.045$  MeV (1980BU15) [recalculated using the (1985WA02) masses for  $^8\text{He}$ ,  $^{16}\text{O}$  and  $^{20}\text{Ne}$ ]. The weighted mean is  $23.989 \pm 0.020$  MeV, which is also the (1985WA02) value.  $^{16}\text{Ne}$  is then bound with respect to decay into  $^{15}\text{F} + \text{p}$  by 0.07 MeV and unbound with respect to  $^{14}\text{O} + 2\text{p}$  by 1.40 MeV (1986AJ04).

1. $^{16}\text{O}(\pi^+, \pi^-)^{16}\text{Ne}$	$Q_m = -24.77$
--	----------------

For ground state cross sections and analyses for  $E_{\pi^+} = 80$  to 292 MeV see (1982AJ01, 1986AJ04). A recent measurement at  $\theta_{\text{lab}} = 5^\circ$  for  $E_{\pi^+} = 140\text{--}292$  MeV has been reported (1990SE11).

Table 16.32: Energy levels of  $^{16}\text{Ne}$ 

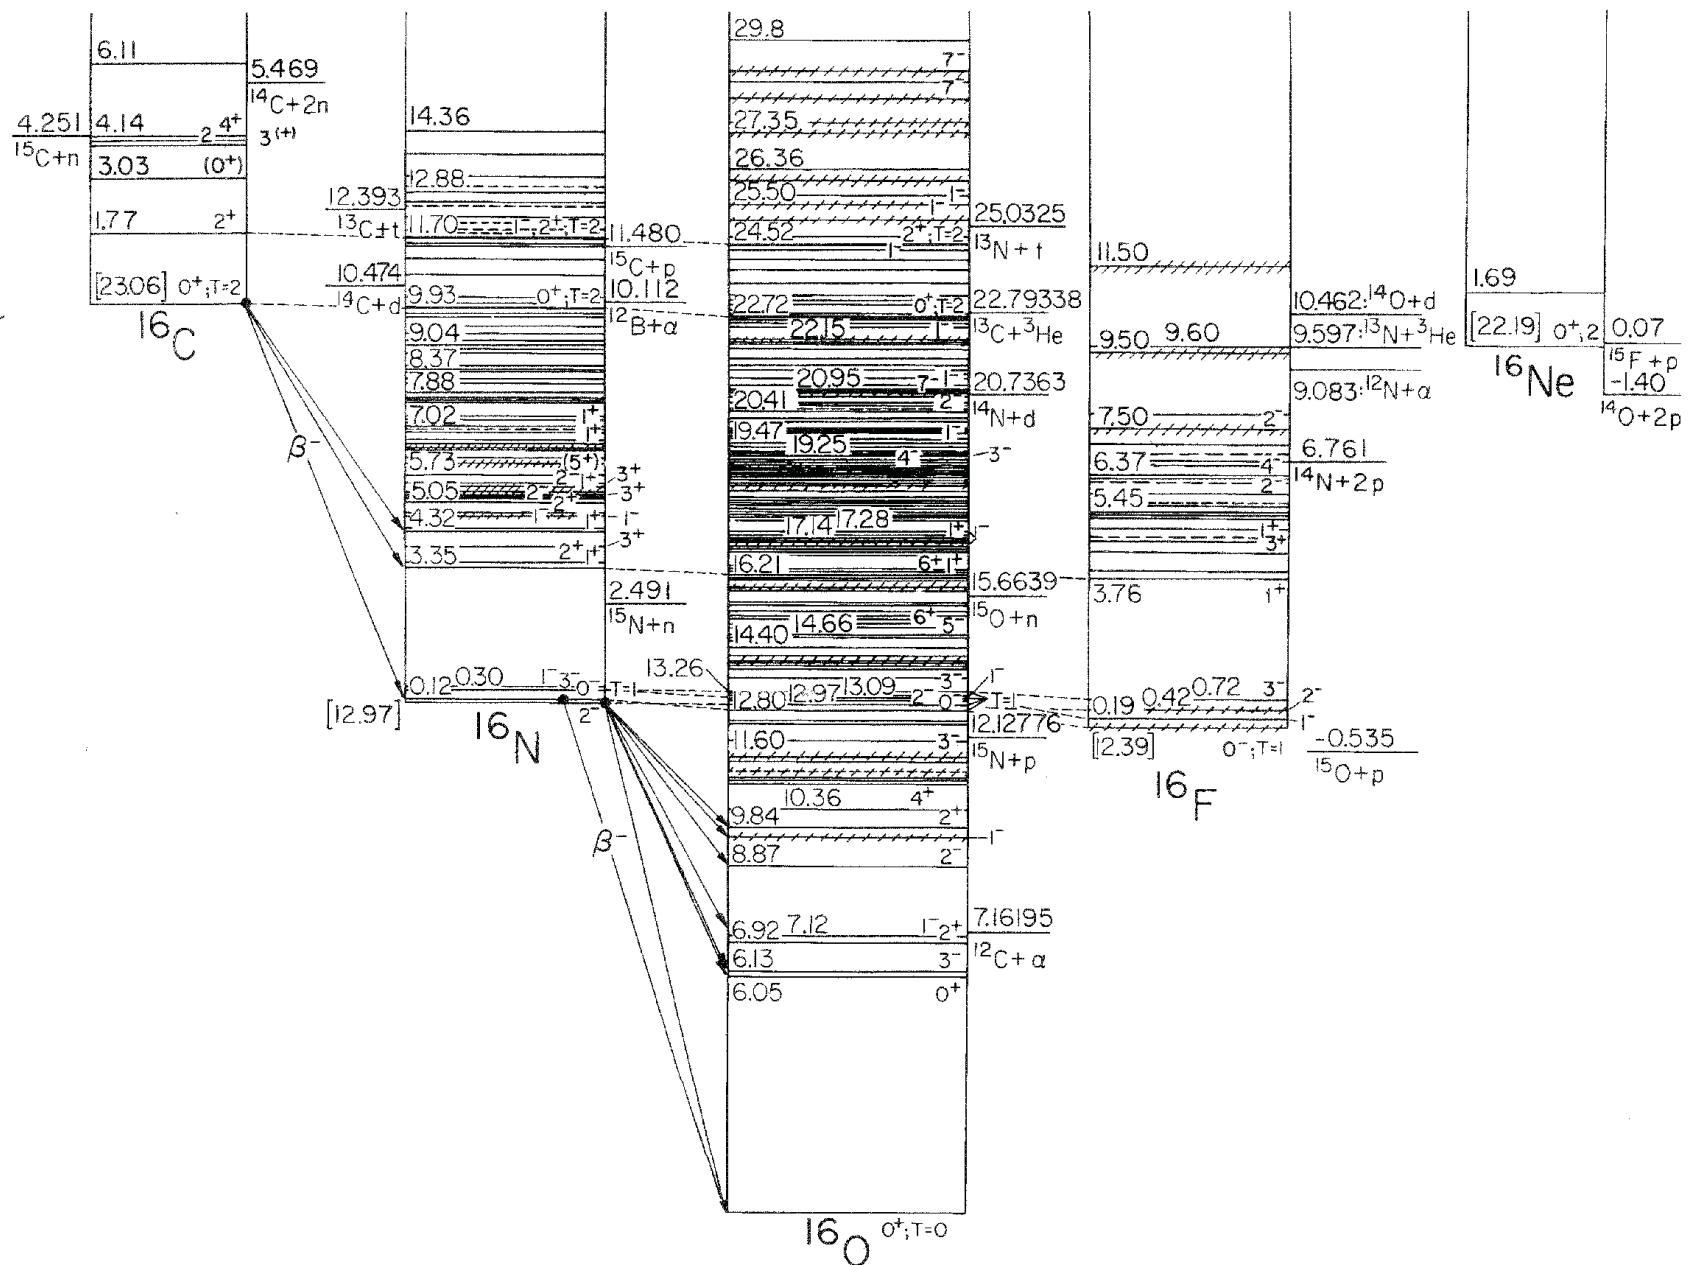

$E_x$ (MeV $\pm$ keV)	$J^\pi; T$	$\Gamma_{\text{c.m.}}$ (keV)	Decay	Reactions
0	$0^+; 2$	$122 \pm 37$	p	1, 2
$1.69 \pm 0.07$	$(2^+); 2$		(p)	2

At  $E_\alpha \approx 117.5$  MeV,  $^{16}\text{Ne}^*(0, 1.69 \pm 0.07)$  are populated, the former with a differential cross section of  $5 \pm 3$  nb/sr at  $8^\circ$ (lab). The  $\Gamma_{\text{c.m.}}$  for the ground state group is  $200 \pm 100$  keV; applying penetrability corrections leads to a total decay width of 5–100 keV. The di-proton branching ratio is 10–90%, with the most probable value being 20%. The cubic term, d, in the IMME (Isobaric Multiplet Mass Equation) is  $8 \pm 5$  keV,  $15 \pm 6$  keV based, respectively, on the masses of  $^{16}\text{Ne}^*(0, 1.69)$ . The first  $T = 2$  states in  $^{16}\text{F}[0^+, 2^+]$  are predicted to lie at  $E_x = 10.08 \pm 0.02$  and  $11.87 \pm 0.03$  MeV ([1978KE06](#)). At  $E_\alpha = 129$  MeV ([1983WO01](#)) find  $\Gamma_{\text{c.m.}}$  for  $^{16}\text{Ne}_{\text{g.s.}} = 110 \pm 40$  keV and the  $d$  and  $e$  coefficients in the IMME are both  $4 \pm 3$  keV.

$^{16}\text{Na}, ^{16}\text{Mg}, ^{16}\text{Al}, ^{16}\text{Si}$   
(not observed)

See ([1986AN07](#)).
