F. Ajzenberg-Selove

University of Pennsylvania, Philadelphia, Pennsylvania 19104-6396

Abstract: An evaluation of $A = 16$–17 was published in *Nuclear Physics A*460 (1986), p. 1. This version of $A = 17$ differs from the published version in that we have corrected some errors discovered after the article went to press. Figures and introductory tables have been omitted from this manuscript. Reference key numbers have been changed to the NNDC/TUNL format.

Table of Contents for $A = 17$

Below is a list of links for items found within the PDF document. Figures from this evaluation have been scanned in and are available on this website or via the link below.

^{17}He, ^{17}Li

(Not illustrated)

Not observed: see (1983ANZQ; theor.).

^{17}Be

(Not illustrated)

This nucleus has not been observed. Its atomic mass excess is calculated to be 70.67 MeV: see (1977AJ02). It is then unstable with respect to breakup into ^{16}Be + n and ^{15}Be + 2n by 3.38 and 3.35 MeV, respectively. See also (1983ANZQ; theor.).

^{17}B

(Not illustrated)

^{17}B has been observed in the 4.8 GeV proton bombardment of uranium: it is particle stable and its ground state J^π is probably $\frac{3}{2}^-$ (1974BO05). Its atomic mass excess is estimated by (1985WA02) to be 44.01 ± 0.70 MeV. It is then stable with respect to decay into ^{15}B + 2n by 1.10 MeV. E_{β^-}(max) for the decay to ^{17}C$_{\text{g.s.}}$ would then be 22.98 MeV. See also (1984MU27) and (1983ANZQ, 1985PO10; theor.).

^{17}C

(Fig. 9)

A Q-value measurement of the ^{48}Ca(^{18}O, ^{17}C)^{49}Ti reaction leads to an atomic mass excess of 21.039 ± 20 keV (1982FI10; $E(^{18}\text{O}) = 112$ MeV) for ^{17}C, using the (1985WA02) a.m.e. values for ^{18}O, ^{48}Ca and ^{49}Ti. See also (1982AJ01). ^{17}C is then stable with respect to ^{16}C + n by 0.73 MeV. E_{β^-}(max) to ^{17}N$_{\text{g.s.}}$ = 13.17 MeV. See also (1984KL06). The half-life of ^{17}C is 202 ± 17 msec (1986CU01). An excited state of ^{17}C is reported at $E_x = 292 \pm 20$ keV [see (1982AJ01)], 295 ± 10 keV (1982FI10). Three closely spaced low-lying states are expected [$J^\pi = \frac{5}{2}^+, \frac{3}{2}^+, \frac{1}{2}^+$] (1982CUZZ): it is not clear which is the assignment of the ground state. See also (1982AJ01), (1982OR1D, 1984HI1A) and (1983ANZQ, 1983FR1A, 1983WI1A, 1984AS1D; theor.).

1. (a) ^{17}N(β^-)^{17}O* → ^{16}O + n $\qquad Q_{\rm m} = 4.557$

   (b) ^{17}N(β^-)^{17}O $\qquad Q_{\rm m} = 8.680$

The half-life of ^{17}N is 4.173 ± 0.004 sec. The decay is principally [see Table 17.3] to the neutron unbound states ^{17}O*(4.55, 5.38, 5.94) [$J^\pi = \frac{3}{2}^-, \frac{3}{2}^-, \frac{1}{2}^-$]. The nature of the decay is in agreement with $J^\pi = \frac{1}{2}^-$ for ^{17}N$_{\rm g.s.}$: see (1982AJ01). For a comparison of the ^{17}N and ^{17}Ne decays see Table 17.4. For GT transition rates see (1983SN03) and (1983RA29). See also (1977FR19).

2. ^{11}B(^{7}Li, p)^{17}N $\qquad Q_{\rm m} = 8.415$

Observed proton groups and γ-rays are displayed in Table 17.5. Table 17.2 shows branching ratio and lifetime measurements.

3. ^{14}C(^{6}Li, ^{3}He)^{17}N $\qquad Q_{\rm m} = -5.697$

At $E(^6{\rm Li}) = 34$ MeV angular distributions have been studied to ^{17}N*(1.91, 2.53, 3.63, 4.10, 5.17) and the results compared with those for the analog reaction to ^{17}O (reaction 16) (1983CU04).

Angular distributions have been reported at $E(^9\text{Be}) = 16.1$ to 20 MeV [see (1982AJ01)] and at $E(^9\text{Be}) = 12.0$ to 27.0 MeV (1981JA09; α_0, α_2). For excitation functions see (1982AJ01) and (1982HU06, 1983JA09). See also (1983VO1A).

8. ^{13}C(α, γ)^{17}O $\quad Q_m = 6.3592$

Assuming $\Gamma_\alpha/\Gamma = 0.45$ for the lower resonance, Γ_{γ_1} for the E1 transition from ^{17}O*(9.15) [$J^\pi = \frac{1}{2}^-$] to ^{17}O*(0.87) [$\frac{1}{2}^+$] is 1.44 ± 0.26 eV. The parameters of ^{17}O*(11.08) are discussed in Table 17.11 (1983RA29).

10. ^{13}C(^{6}Li, d)^{17}O $\qquad Q_{\rm m} = 4.884$

At $E(^{6}\text{Li}) = 35.5$ MeV angular distributions are reported to ^{17}O*(13.58 $\pm$ 0.02) which is strongly populated. Comparisons with ^{12}C(^{6}Li, d)^{16}O*(16.29) and with the results of reaction 11 here suggest that the peak corresponding to ^{17}O*(13.58) contains a state or states of spin $\frac{11}{2}^{-}$, $\frac{13}{2}^{-}$, or both, based on ^{16}O*(16.29) (1978CL08). (d, α) angular correlations [$E(^{6}\text{Li}) = 26$, 29 and 34 MeV] indicate the involvement of ^{17}O states at 13.6 ± 0.1 [$l = 6$], 14.15 ± 0.1[5], 15.1 ± 0.1[5], 15.95 ± 0.15[5], 16.6 ± 0.15[6], 17.1 ± 0.15[6], 19.6 ± 0.15[7], 20.2 ± 0.15[7], 21.2[7] and 22.1 MeV, $\Gamma \approx 0.1$, 0.5, 0.7, 0.25 and 0.25 MeV for ^{17}O*(14.2, 15.1, 16.0, 19.6, 20.2) (1978AR15). See, however, (1984CA39). For the earlier work see Table 17.7 in (1977AJ02).

11. ^{13}C(^{7}Li, t)^{17}O $\qquad Q_{\rm m} = 3.891$

At $E(^{7}\text{Li}) = 35.7$ MeV angular distributions are reported to ^{17}O*(3.06) and to ^{17}O*(13.58) which is preferentially populated (see discussion in reaction 10). Narrow states at $E_{\rm x} = 14.86$, 18.17 and 19.24 MeV are also strongly excited (1978CL08). For the earlier work see Table 17.7 in (1977AJ02).

12. ^{13}C(^{13}C, ^{9}Be)^{17}O $\qquad Q_{\rm m} = -4.2884$

At $E(^{13}\text{C}) = 105$ MeV states of ^{17}O with $E_{\rm x} = 3.9$, 5.2, 5.8 ± 0.1, 7.2, 7.6, 8.4 ± 0.06, 8.9, 9.8 ± 0.07, 10.55 ± 0.06, 12.1 ± 0.06, 13.3, 14.6 and 18.9 ± 0.14 MeV are reported (1979BR04).

13. ^{13}C(^{16}O, ^{12}C)^{17}O $\qquad Q_{\rm m} = -0.8027$

Angular distributions involving ^{17}O*(0, 0.87) have been studied for $E(^{16}\text{O}) = 12$ to 25 MeV: see (1977AJ02, 1982AJ01). See also (1979GO1C).

14. ^{14}C(^{3}He, γ)^{17}O $\qquad Q_{\rm m} = 18.7605$

The capture cross sections at 90° for γ_0 and for γ_1 have been studied for $E(^{3}\text{He}) = 3.2$ to 7.5 MeV and angular distributions of the γ-rays have been studied at the six observed resonances: see Table 17.9.

16. ^{14}C(^{6}Li, t)^{17}O $\quad Q_m = 2.9649$

At $E(^6\text{Li}) = 34$ MeV angular distributions have been reported to ^{17}O*(0, 0.87, 3.06, 3.84, 4.55, 5.70, 6.36, 7.17(u), 7.38(u), 7.76, 8.20, 8.47(u), 9.18(u), 9.71, 9.87(u), 10.42, 11.24, 11.82, 12.01, 12.27, 13.00(u), 13.6(u), 14.76(u), 15.20, 16.3(u)) (1981CU11, 1983CU02, 1983CU04; u = unresolved). (1983CU02) suggests evidence for two 3p-2h bands in ^{17}O and (1983CU04) for analog states in ^{17}N–^{17}O. See these two papers for spectroscopic factors.

17. ^{14}N(t, γ)^{17}O $\quad Q_m = 18.6226$

The excitation functions for γ_0 and γ_1 have been measured for $E_t = 0.8$ to 3.3 MeV: broad resonances are observed at 2.2 and 2.8 MeV in the γ_0 cross section, and at 2.4 and 2.8 MeV in the γ_1 cross section. Both also exhibit a structure at 1.5 MeV. The data are consistent with states at $E_x = 19.76 \pm 0.06$ [$J = \frac{3}{2}$], 20.39 ± 0.05 [$\frac{5}{2}$, $\frac{7}{2}^-$], 20.58 ± 0.05 [$\frac{1}{2}$] and 21.05 ± 0.05 MeV [$\frac{3}{2}$] with $\Gamma = 0.55 \pm 0.05$, 0.66 ± 0.07, 0.57 ± 0.08 and 0.47 ± 0.06 MeV, and possibly with a state at ≈ 19.3 MeV. $\Gamma_{\gamma_0} > 1.0$, 4.3 and 5.8 eV for ^{17}O*(19.8, 20.4, 21.1) and $\Gamma_{\gamma_1} > 2.3$, 5.1 and 6.5 eV for ^{17}O*(19.8, 20.6, 21.1) (1980LI05). For the charged particle channels see (1977AJ02).

18. (a) ^{14}N(α, p)^{17}O $\qquad Q_m = -1.1914$

(b) ^{14}N(α, αp)^{13}C $\qquad Q_m = -7.55062$

Angular distributions have been measured for ^{17}O states with $E_x < 7.6$ MeV in the range $E_\alpha = 8.1 \rightarrow 33.3$ MeV: see a listing of the references in (1971AJ02). The sequential decay (reaction (b)) appears to take place via ^{17}O states with $8.46 \leq E_x \leq 13.57$ MeV. Those involved are believed to have $J \geq \frac{5}{2}$, $\Gamma_\alpha/\Gamma \geq 0.6$.

19. (a) ^{14}N(^{6}Li, ^{3}He)^{17}O $\qquad Q_m = 2.827$

(b) ^{14}N(^{6}Li, ^{3}Heα)^{13}C $\qquad Q_m = -3.5322$

Angular distributions (reaction (a)) and angular correlations (reaction (b)) have been measured at $E(^6\text{Li}) = 36$ MeV involving ^{17}O*(8.48, 10.7, 12.0, 13.53, 14.88). Comparisons are made with the results in the analog reaction [(^{6}Li, t)] involving states in ^{17}F (1984ET01). [Comment: compare the experimental resolution with the density of states]. For the earlier work see (1982AJ01).

20. (a) ^{15}N(d, n)^{16}O $\qquad Q_m = 9.9030 \qquad E_b = 14.0466$

(b) ^{15}N(d, p)^{16}N $\qquad Q_m = 0.266$

Excitation functions have been measured for $E_d = 0.5$ to 5.9 MeV (reaction (a)) and 0.3 to 6.3 MeV (reaction (b)): see (1977AJ02). Unresolved structures are observed in the neutron data. There is some evidence for structures at $E_d = 1.8$ MeV [p_0, p_1, p_3] and 2.4 MeV [p_2] [^{17}O*(15.6, 16.2)]: see (1982AJ01). See also (1984HE20) and ^{16}N, ^{16}O here.

21. ^{15}N(d, d)^{15}N $\qquad E_b = 14.0466$

Excitation functions for d_0 have been measured for $E_d = 1.4$ to 6.25 MeV. Structures are reported at ≈ 1.4 and 1.8 MeV: see (1982AJ01).

22. ^{15}N(d, α)^{13}C $\qquad Q_m = 7.6874 \qquad E_b = 14.0466$

Yield curves have been measured for $E_d = 0.8$ to 2.7 MeV. Structures are reported at $E_d = 1.06$, 1.25 and ≈ 1.8 MeV. The latter has $\Gamma \approx 300$ keV: see (1982AJ01). See also (1986SA41; applied).

However *these values do not take into account any error in the measurement of* $[\Gamma_{\alpha_0}\Gamma_{n_0}]^{1/2}/\Gamma_{tot}$ [F.C. Barker, private communication]. I am also indebted to C. Then $\Gamma_{\alpha_0} = 0.3$ keV and $\Gamma_{\gamma_1} = 12$ eV. I am indebted to Prof. McDonald for his comments)].

23. ^{15}N(^{3}He, p)^{17}O $\qquad Q_{\rm m} = 8.5531$

Observed proton groups are displayed in Table 17.10. For the parameters of the first $T = \frac{3}{2}$ state see Table 17.11.

24. ^{15}N(α, d)^{17}O $\qquad Q_{\rm m} = -9.8001$

At $E_\alpha = 45.4$ MeV, the deuteron spectrum is dominated by the groups corresponding to states with $E_{\rm x} = 7.742 \pm 0.020$ and 9.137 ± 0.030 MeV. These states are assigned $J^\pi = (\frac{11}{2}^-)$ and $(\frac{9}{2}^-)$ and arise from a dominant $({\rm d}_{5/2})^2_5{\rm p}^{-1}_{1/2}$ configuration: see (1977AJ02).

$$\sigma_{\rm capt.} = 202 \pm 28\ \mu{\rm b}\ \text{(1977MC05). See also (1981MUZQ).}$$

At thermal energies the branchings via ^{17}O*(0.87, 3.05) are (18 ± 3) and $(82 \pm 3)\%$; $E_\gamma = 870.89 \pm 0.22$ and 2184.47 ± 0.12 keV [the latter leads to $E_{\rm x} = 3055.43 \pm 0.19$ keV for ^{17}O*(3.09); A.H. Wapstra, private communication]. The cross section for two-photon emission $\sigma_{2\gamma} < 3 \pm 19\ \mu$b for $1200 < E_\gamma < 2943$ keV. The two-photon branching ratio is $(1.6 \pm 10) \times 10^{-2}$ (1977MC05).

27. ^{16}O(n, n)^{16}O $\qquad E_{\rm b} = 4.1436$

The scattering amplitude (bound) $a = 5.805 \pm 0.005$ fm, $\sigma_{\rm free} = 3.761 \pm 0.007$ b (1979KO26). See also (1981MUZQ). Resonances observed in the elastic scattering and in the (n, α) reaction are displayed in Table 17.12. A two-channel R-matrix analysis finds that five states contain nearly 100% of the 1d$_{3/2}$ strength and have their eigenenergy at $E_{\rm x} \approx 5.7$ MeV [the dominant state is ^{17}O*(5.08)]. Spectroscopic factors are deduced for 26 states in ^{17}O for $4.5 < E_{\rm x} < 9.5$ MeV [see Table 17.12 in (1977AJ02)]: the sum of these factors is 1% for $J^\pi = \frac{1}{2}^+$, 5% for $\frac{1}{2}^-$, 12% for $\frac{3}{2}^-$, 99% for $\frac{3}{2}^+$, 0.1% for $\frac{5}{2}^+$, 1% for $\frac{5}{2}^-$ and 14% for $\frac{7}{2}^-$. $T = \frac{3}{2}$ resonances are discussed by (1981HI01): see Tables 17.11 and 17.12.

Cross-section measurements are listed in Table 17.10 of (1971AJ02) and in (1977AJ02, 1982AJ01). An optical model analysis of angular distributions leads to predictions of σ_R and σ_T for $E_n = 6$ to 9 MeV (1983DA22). A_y measurements for n_0 have been carried out at $E_n = 5$ to 17 MeV (1985ANZX) and at 23 MeV (1985LA13).

[b] Used to evaluate the widths.

[c] These levels were unresolved and were analyzed as a group.

[d] However (D.M. Manley, private communication) reports that ^{17}O*(6.86, 6.97) had form factors which were, respectively, characteristic of C2 and of C3 leading to $J^{\pi} = \frac{1}{2}^+ \rightarrow \frac{9}{2}^+[\frac{1}{2}^+$ excluded by ^{16}O(n, n) results] and $\frac{1}{2}^- \rightarrow \frac{11}{2}^-$ for these two states. The widths shown are from the work of (1978KI01) based on an analysis of unresolved states.

[e] However (D.M. Manley, private communication) reports a form factor consistent with C2 and therefore $J^{\pi} = \frac{7}{2}^+, \frac{9}{2}^+$ for ^{17}O*(7.58). The group to ^{17}O*(8.47) is very strong; the form factor is consistent with C2.

[f] (D.M. Manley, private communication): $E_x = 8.90 \pm 0.02$ MeV. The group corresponding to ^{17}O*(9.15) is weak at 90° and strong at 160°, consistent with a large M2 strength.

[g] (1983RA27). [Comment: See, however, the density of states in this excitation region.]

[h] $T = \frac{3}{2}$.

[i] If pure M2. If pure C1, B(C1$\uparrow$) $= (1.0 \pm 0.4) \times 10^{-2}$ and $(0.4 \pm 0.2) \times 10^{-2}$ $e^2 \cdot$ fm^2, respectively for ^{17}O*(12.47, 13.00) (1983RA27).

[j] ^{17}O*(14.75) is suggested to have $J^{\pi} = \frac{9}{2}^-$ from analog states considerations. If the transition is M1 ^{17}O*(15.10) has $J^{\pi} = (\frac{3}{2}, \frac{5}{2}, \frac{7}{2})^+$ (1983RA27).

[k] [(1986MA48): $E_e = 180$ to 268 MeV]. The values for B(M4$\uparrow$) are based on 1513 ± 76 $e^2 \cdot$ fm^8 for ^{16}O*(18.98) [$J^{\pi} = 4^-$].

[l] Weakly excited.

[m] No other states are observed with $21 < E_x < 23.5$ MeV.

Monoenergetic photons with $E_\gamma = 8.5$ to 39.7 MeV have been used to measure the (γ, n) and the (γ, 2n) [above 10 MeV] cross sections. The giant dipole resonance, 6 MeV broad, is centered at 23 MeV; a pigmy resonance is also observed at 13 MeV. The pigmy resonance [$J^\pi = \frac{3}{2}^-$] decays primarily to ^{16}O$_{\text{g.s.}}$. Above $E_x \approx 17$ MeV nearly all of the decay is to excited states of ^{16}O. Four resonances have been inferred at $E_x = 10.5$, 14.0, 16.6 and 21.0 MeV with $J^\pi = \frac{5}{2}^-, \frac{3}{2}^-, \frac{7}{2}^-$ and $\frac{7}{2}^-$, respectively (1985JU02). Most of the GDR strength decays to $T = 1$ states in ^{16}O: this implies a $T = \frac{3}{2}$ assignment for the main part of the GDR. A broad structure, of $T = \frac{1}{2}$ nature, with $28 < E_x < 36$ MeV is also reported (1980JU01). For radiative widths see Table 17.13 in (1982AJ01). See also (1983RO1J) and (1981HO1H, 1982JU03, 1985PY01).

37. ^{17}O(e, e)^{17}O

The ^{17}O charge radius, $\langle r^2 \rangle^{1/2} = 2.710 \pm 0.015$ fm (1978KI01). The r.m.s. radius of the 1d$_{5/2}$ neutron orbit is calculated to be 3.56 ± 0.09 fm (1982HI01). Inelastic scattering is reported to a number of ^{17}O states: see Tables 17.13 and 17.14. Form factor measurements have been made at 90° and 160° to all the states with $E_x < 7.8$ MeV and to 45 other states with $E_x \leq 20.7$ MeV (1986MA48; D.M. Manley, private communication).

38. ^{17}O($\pi^{\pm}$, $\pi^{\pm}$)^{17}O

At $E_{\pi^{\pm}} = 164$ MeV angular distributions to ^{17}O*(3.85, 4.55, 5.22, 5.69, 7.76, 8.1, 8.4, 15.7, 17.1) have been analyzed by DWBA. Evidence is suggested for E2 strength near 8 MeV and for M4 strength to the two states at $E_x = 15.7$ and 17.1 MeV (1984BL17). [See, however, caveat on p. 1900 of that reference, and the density of states above $E_x = 5$ MeV in Table 17.7.]

For reaction (b) see (1982AJ01). See also ^{20}Ne in (1987AJ02) and (1981CO15, 1985HA11; theor.).

(b) ^{17}O(^{13}C, ^{13}C)^{17}O
(c) ^{17}O(^{14}C, ^{14}C)^{17}O

Elastic angular distributions (reactions (a) and (b)) have been reported at $E(^{17}\text{O}) = 30.5$ to 33.8 MeV [see (1982AJ01)] and at $E(^{17}\text{O}) = 40$ to 70 MeV (1986FR04; also ^{17}O*(0.87)) and 85.4, 120 and 140 MeV (1982HE07). For fusion cross section and yield measurements see (1982AJ01) and (1982HE07, 1983FR17, 1985BE40, 1985BE37, 1986FR04). 44. (a) ^{17}O(^{16}O, ^{16}O)^{17}O
(b) ^{17}O(^{18}O, ^{18}O)^{17}O

Angular distributions involving ^{17}O*(0, 0.87) in reaction (a) have been studied at $E(^{16}\text{O}) = 22$ to 32 MeV and $E(^{17}\text{O}) = 25.7$ to 32.0 MeV [see (1977AJ02)] as well as at $E(^{17}\text{O}) = 22$ MeV (1983BU08; elastic $\sigma(\theta)$ to $\pm 1\%$). A model independent value of 0.82 ± 0.07 is obtained for the coupling constant of the $1d_{5/2}$ neutron in ^{17}O. A review of magnetic electron scattering on ^{17}O then leads to a spectroscopic factor $S = 1.03 \pm 0.07$. This corresponds to $(91 \pm 7)\%$ of the single-particle value (1983BU08). For fusion cross sections see (1982AJ01) and (1986TH01). The elastic scattering angular distribution in reaction (b) has been reported at $E(^{17}\text{O}) = 36$ MeV: see (1982AJ01). [b] May be a doublet: compare Table 17.19 and 17.21.

Excitation functions for γ_{0+1}, γ_2 and γ_3 have been studied for $E(^3\text{He}) \approx 3$ to 18 MeV. Resonances are reported corresponding to ^{17}F states at 20.1 ± 0.2 (γ_2) [$\Gamma = 1.07 \pm 0.16$ MeV], 20.4 ± 0.1 (γ_1) [0.7 ± 0.1] and 21.3 ± 0.1 MeV (γ_1) [0.9 ± 0.1] (1983WA05): see Table 17.19 in (1982AJ01). For neutron and charged-particle channels see reaction 6 in (1982AJ01).

   (b) ^{14}N(^{6}Li, tα)^{13}N $\qquad Q_m = -5.7713$

Angular distributions (reaction (a)) have been measured at $E(^6\text{Li}) = 36$ MeV involving ^{17}F*(8.43, 10.7, 11.9, 13.51, 14.84). Comparisons are made with the results in the analog reaction (reaction 19) in ^{17}O (1984ET01). [Comment: compare the experimental resolution with the density of states]. For the earlier work see (1982AJ01).

[a] See also Table 17.19 and Table 17.20 in (1982AJ01).

[b] γ_0 and γ_1 correspond to transitions to ^{17}F*(0, 0.50), respectively.

[c] These Γ_γ are based on J^π and Γ_{p_0}/Γ determinations quoted by (1975HA06). The B(E1) values for these four states are 4.7 ± 2.0, 5.4 ± 1.6, 1.2 ± 0.8 and $4.4 \pm 2.3[\times 10^{-3}]e^2 \cdot \text{fm}^2$.

[d] See the text of reaction 6 for discussion of the observed pigmy and giant resonances (1975HA07).

[e] See also Table 17.18 in (1977AJ02).

5. ^{15}N(^{3}He, n)^{17}F $\qquad Q_m = 5.0099$

Angular distributions have been reported to most of the states of ^{17}F with $E_x < 8.1$ MeV at $E(^3\text{He}) = 3.8$ and 4.8 MeV. Neutron groups have also been reported to ^{17}F states at $E_x = 11.195 \pm 0.007$, 12.540 ± 0.010 and 13.059 MeV, with $\Gamma < 20$, < 25 and < 25 keV, respectively. Angular distributions at $E(^3\text{He}) = 10.36$ and 11.88 MeV lead to $J^\pi = \frac{1}{2}^-$ for ^{17}F*(11.20)[$L = 0$], $\frac{3}{2}^-$ or $\frac{5}{2}^-$ for ^{17}F*(12.54) and ($\frac{3}{2}^-$, $\frac{5}{2}^-$) for ^{17}F*(13.06). These three states are probably the first three $T = \frac{3}{2}$ states in ^{17}F (1969AD02). The branching ratios for transitions to ^{16}O*(0, 6.05, 6.13) for ^{17}F*(11.20) and for the analog $T = \frac{3}{2}$ state in ^{17}O are displayed in Table 17.11: the ratios of the reduced widths are quite different in the two mirror nuclei. See (1977AJ02) for references.

6. ^{16}O(p, γ)^{17}F $\qquad Q_m = 0.6005$

At low energies the direct capture to ^{17}F*(0, 0.50) is observed. Extrapolation of cross-section data leads to $S(0) \approx 8$ keV · b: see (1977AJ02). In addition to two $T = \frac{1}{2}$ resonances, five resonances corresponding to $T = \frac{3}{2}$ states are observed in the γ_1 and $\gamma_0 + \gamma_1$ yields: see Table 17.18 for the reported parameters. The lowest $T = \frac{3}{2}$ states of even parity at $E_x = 13.27$ and 14.02 MeV [$J^\pi = (\frac{1}{2}^+)$ and $\frac{5}{2}^+$] (see Table 17.19) are not observed here: $\Gamma_\gamma \leq 7$ and ≤ 11.8 eV, respectively (1975HA06).

The $(\gamma_0 + \gamma_1)$ yield at 90° has been studied for $E_p = 15.75$ to 31.66 MeV: it shows the giant dipole resonance centered at $E_x = 22$ MeV with a width of ≈ 5 MeV and a pigmy resonance centered at 17.5 MeV. The integrated strength of the, mainly $T = \frac{1}{2}$, giant resonance is 10 MeV · mb: the observed strength distribution is in good agreement with odd parity 2p-1h, 1p excitation calculations. The pigmy resonance is due to $f_{7/2} \rightarrow d_{5/2}$. The main $f_{7/2}$ strength lies in two states at $E_x = 16.9$ and 18.0 MeV (1975HA07). See also (1982AN1D, 1982BE29, 1983RA1G, 1984JEZY), (1982BA80, 1984BO1Q; astrophysics), (1985BL1B, 1986WE1D) and (1982DU1A, 1984PE02; theor.).

(b) ^{16}O(p, 2p)^{15}N $Q_m = -12.1276$

(c) ^{16}O(p, pn)^{15}O $Q_m = -15.6639$

(d) ^{16}O(p, pα)^{12}C $Q_m = -7.16195$

Yield curves for elastic protons, protons scattered to ^{16}O*(6.05, 6.13, 6.92, 7.12, 8.87) and for γ-rays from ^{16}O*(6.13, 6.92) have been studied at many energies up to $E_p = 46$ MeV: see (1971AJ02, 1977AJ02, 1982AJ01). The observed resonances are displayed in Table 17.19. Absolute $\sigma(\theta)$ [$\theta = 110°$ to $160°$] have been measured for $E_p = 0.60$ to 2.00 MeV to ±5% (1983BR11). Cross sections for bremsstrahlung emission are reported in the vicinity of the $E_p = 2.66$ MeV resonance by (1983TRZZ). The cross sections of the 6.13 MeV γ-ray at $E_p = 23.7$ and 44.6 MeV have been measured by (1981NA14), and (1979SC07) report the σ_t for $E_p = 190$ to 558 MeV. See also (1982AJ01).

A_y measurements have beem recently reported at $E_{\vec{p}} = 35$ MeV (1986OH1C; to ^{16}O*(10.96, 12.80)), 65 MeV (1982SA19; p_0), 65 MeV (1984HO17; to ^{16}O*(10.96, 12.80)), 135 and 180 MeV (1983HYZZ; to ^{16}O*(8.87)), 180 MeV (1983FIZW; to many states including ^{16}O*(11.10)) and 200 MeV (1985GL01; p_0). At $E_{\vec{p}} = 318$ and 498 MeV (1983LOZW, 1986LO1D) have measured A_y and spin transfer observables for the p_0, p_2, p_3 and p_4 groups. Polarization transfer coefficients have been studied at $E_{\vec{p}} = 200$ MeV to the 4^- states ^{16}O*(17.79, 19.81) [$T = 0$] and ^{16}O*(18.98) [$T = 1$] (1985WIZW, 1986OL1A). The spin rotation parameter Q has been measured for the elastic scattering at $E_{\vec{p}} = 65$ MeV by (1986SA1J), at 200 MeV by (1985STZW, 1986ST1G) [see (1986ST1F) for polarization transfer coefficients for ^{16}O*(17.79, 18.98, 19.81)] and at 800 MeV by (1986FE01). See also (1986GL1G). For the earlier work see (1982AJ01).

Uncertainties in E_p (below 12.7 MeV) have been increased because of a possible error in calibrating the magnet used in many of the measurements reported in (1971AJ02). See also (1964DA02). 8. ^{16}O(p, n)^{16}F $Q_m = -16.199$ $E_b = 0.6005$

The analyzing power for the transition to the 4^- state ^{16}F*(6.37) has been measured at $E_{\vec{p}} =$ 135 MeV (1982MA11). See also ^{16}F.

Parameters of the first excited state of ^{17}F are $E_{\rm x} = 495.33 \pm 0.10$ keV, $\tau_{\rm m} = 407 \pm 9$ psec: see (1971AJ02). See also Table 17.21 in (1971AJ02). For polarization measurements see (1981LI23) and ^{18}F in (1983AJ01). See also (1983CR1A).

13. ^{16}O(^{3}He, d)^{17}F $Q_{\rm m} = -4.8931$

[Note known density of states.] The group to ^{17}F*(4.84) has $\Gamma = 1.8 \pm 0.05$ MeV (1985PU1A). For a discussion of Gamow-Teller transition probabilites see (1985WA24). ^{17}Ne
(Figs. 8 and 9)

GENERAL: (See also (1982AJ01).)

Theory and reviews: (1983ANZQ, 1983AU1B, 1985AN28).

1. (a) ^{17}Ne(β^+)^{17}F* $\rightarrow$ ^{16}O + p $\qquad Q_{\rm m} = 13.93$
   (b) ^{17}Ne(β^+)^{17}F $\qquad Q_{\rm m} = 14.53$

The half-life of ^{17}Ne is 109.0 ± 1.0 msec (1971HA05). Earlier values (see (1971AJ02)) gave a mean value of 108.0 ± 2.7 msec. The decay is primarily to the proton unstable states of ^{17}F at 4.70, 5.52 and 6.04 MeV with $J^\pi = \frac{3}{2}^-, \frac{3}{2}^-$ and $\frac{1}{2}^-$: see Table 17.21. The super-allowed decay to the analog state [^{17}F*(11.20)] has $\log ft = 3.29^{+0.04}_{-0.07}$. The character of the decay leads to $J^\pi = \frac{1}{2}^-$ for ^{17}Ne$_{\rm g.s.}$ (1971HA05). See Table 17.3 for a comparison of the mirror ^{17}N and ^{17}Ne decays and Table 17.11 for the decay of ^{17}F*(11.20). See also (1983RA29).

^{17}Na
(Not illustrated)

^{17}Na has not been observed: its mass excess is predicted to be 35.61 MeV by (1966KE16). It is then unbound with respect to breakup into ^{16}Ne + p by 4.3 MeV and with respect to breakup into ^{14}O + 3p by 5.7 MeV. See also (1983ANZQ, 1985AN28; theor.).

[a] (1971HA05). See also Table 17.23 in (1971AJ02). I am indebted to Drs. H.T. Richards and E.K. Warburton for their comments.

[b] log ft values calculated by (1971HA05) using an atomic mass excess of 16.517 ± 0.026 MeV [and $\tau_{1/2} = 109.0 \pm 1.0$ msec] rather than the presently adopted 16.48 ± 0.05 MeV. Since this energy difference leads to quite small changes, the original calculations are quoted here. However, Table 17.4 (which compares the analog decays) shows corrected ft values.

[c] E.K. Warburton calculates $E_x = 4613 \pm 15$ keV by weighing of the Fermi function over the width of this level.

[d] See also Table 17.11.

[e] A proton group with $E_{c.m.} = 2.83$ MeV has been observed: the level in ^{17}F to which it corresponds is not known.

[f] Calculated branchings, based on the mirror ^{17}N decay.
